#### Abstract

Set constraints are relations between sets of terms. They have been used extensively in various applications in program analysis and type inference. Recently, several algorithms for solving general systems of positive set constraints have appeared. In this paper we consider systems of mixed positive and negative constraints, which are considerably more expressive than positive constraints alone. We show that it is decidable whether a given such system has a solution. The proof involves a reduction to a number-theoretic decision problem that may be of independent interest.

## 1 Introduction

Set constraints are formal inclusions or negated inclusions between expressions representing subsets of $T_{\Sigma}$, the set of ground terms over a finite ranked

[^0]alphabet $\Sigma$. Formally, a positive set constraint is of the form $E \subseteq F$ and a negative set constraint is of the form $E \nsubseteq F$, where $E$ and $F$ are expressions built from a set $X=\{x, y, \ldots\}$ of variables ranging over subsets of $T_{\Sigma}$, the usual set-theoretic operators $0,1, \cup, \cap$, and $\sim$, and an $n$-ary set operator $f$ for each $n$-ary symbol $f \in \Sigma$ with semantics
$$
f\left(A_{1}, \ldots, A_{n}\right)=\left\{f t_{1} \ldots t_{n} \mid t_{i} \in A_{i}, 1 \leq i \leq n\right\}
$$

A system $\mathcal{S}$ of constraints is satisfiable if there is an assignment of subsets of $T_{\Sigma}$ to the variables satisfying all the constraints in $\mathcal{S}$.

Set constraints have numerous applications in program analysis and type inference $[3,4,7,14,15,18,19,20,22]$. Most of these systems deal with positive constraints only. Several algorithms for determining the satisfiability of general systems of positive constraints have appeared [1, 5, 6, 11, 13]. In [1], the satisfiability problem for a system $\mathcal{S}$ of positive constraints is shown to be equivalent to deciding whether a certain finite hypergraph constructed from $\mathcal{S}$ has an induced subhypergraph that is closed (see Section 4). This characterization is used to obtain an exhaustive hierarchy of complexity results depending on the number of elements of $\Sigma$ of each arity.

In this paper we consider systems of mixed positive and negative constraints. Negative constraints considerably increase the power of the constraint language and have important applications in program analysis. For example, in [3, 4], opportunities for program optimization are identified by an ad hoc technique for checking the satisfiability of systems of negative constraints. Set constraints with only nullary symbols correspond to Boolean algebras over a finite set of atoms; in [17] general results on solving negative constraints in arbitrary Boolean algebras are given.

In this paper we give a general decision procedure for determining whether a given system of mixed positive and negative set constraints over an arbitrary signature is satisfiable. The proof reduces the satisfiability problem to a reachability problem involving Diophantine inequalities which may be of independent interest. We reduce the satisfiability problem to the Diophantine problem and then show that the Diophantine problem is decidable. The proof has a nonconstructive step involving Dickson's Lemma and does not give any complexity bounds.

The decidability result for systems of mixed positive and negative set constraints was obtained independently by Gilleron, Tison, and Tommasi [12]
using automata-theoretic techniques. Stefánsson [21] has subsequently shown that the Diophantine satisfiability problem is $N P$-complete and the satisfiability problem for systems of mixed positive and negative set constraints is complete for NEXPTIME. Charatonik and Pacholski [8] have given an alternative proof of this result based on the approach of [6] involving monadic logic, and have extended the result to include projections [9]. Relationships between these various approaches have been drawn in [16].

## 2 Set Expressions and Set Constraints

There is some variation in the literature regarding the definition of set expressions and set constraints, depending on the operations allowed. The following definition is taken from [1].

Let $\Sigma$ be a finite ranked alphabet consisting of symbols $f$, each with an associated arity arity $(f) \in \mathbb{N}$. Symbols in $\Sigma$ of arity $0,1,2$, and $n$ are called nullary, unary, binary, and n-ary, respectively. Nullary elements are often called constants. The set of elements of $\Sigma$ of arity $n$ is denoted $\Sigma_{n}$.

The set of ground terms over $\Sigma$ is denoted $T_{\Sigma}$. This is the smallest set such that if $t_{1}, \ldots, t_{n} \in T_{\Sigma}$ and $f \in \Sigma_{n}$, then $f t_{1} \ldots t_{n} \in T_{\Sigma}$. If $X=\{x, y, \ldots\}$ is a set of variables, then $T_{\Sigma}(X)$ denotes the set of terms over $\Sigma$ and $X$, considering the elements of $X$ as symbols of arity 0 .

Let $\mathrm{B}=(\cup, \cap, \sim, 0,1)$ be the usual signature of Boolean algebra. Other Boolean operators such as $\oplus$ (symmetric difference) are defined from these as usual. Let $\Sigma+\mathrm{B}$ denote the signature consisting of the disjoint union of $\Sigma$ and B. A set expression over $X$ is any element of $T_{\Sigma+\mathrm{B}}(X)$. The following is a typical set expression:

$$
f(g(x \cup y), \sim g(x \cap y)) \cup a
$$

where $f \in \Sigma_{2}, g \in \Sigma_{1}, a \in \Sigma_{0}$, and $x, y \in X$. We use $E, F, \ldots$ to denote set expressions. A Boolean expression over $X$ is any element of $T_{\mathrm{B}}(X)$.

A positive set constraint is a formal inclusion $E \subseteq F$, where $E$ and $F$ are set expressions. We also allow equational constraints $E=F$, although inclusions and equations are interdefinable: $E \subseteq F$ is equivalent to $E \cup F=$ $F$, and $E=F$ is equivalent to $E \oplus F \subseteq 0$. A negative set constraint is the negation of a positive set constraint: $E \nsubseteq F$ or $E \neq F$.

We interpret set expressions over the powerset $2^{T_{\Sigma}}$ of $T_{\Sigma}$. This forms an algebra of signature $\Sigma+B$ where the Boolean operators have their usual settheoretic interpretations and elements $f \in \Sigma_{n}$ are interpreted as functions $f:\left(2^{T_{\Sigma}}\right)^{n} \rightarrow 2^{T_{\Sigma}}$ such that

$$
f\left(A_{1}, \ldots, A_{n}\right)=\left\{f t_{1} \ldots t_{n} \mid t_{i} \in A_{i}, 1 \leq i \leq n\right\}
$$

A set assignment is a map

$$
\sigma: X \quad \rightarrow \quad 2^{T_{\Sigma}}
$$

assigning a subset of $T_{\Sigma}$ to each variable in $X$. Any set assignment $\sigma$ extends uniquely to a $(\Sigma+B)$-homomorphism

$$
\sigma: T_{\Sigma+\mathrm{B}}(X) \rightarrow 2^{T_{\Sigma}}
$$

by induction on the structure of the set expression in the usual way. The set assignment $\sigma$ satisfies the positive constraint $E \subseteq F$ if $\sigma(E) \subseteq \sigma(F)$, and satisfies the negative constraint $E \nsubseteq F$ if $\sigma(E) \nsubseteq \sigma(F)$. We write $\sigma \models \varphi$ if the set assignment $\sigma$ satisfies the constraint $\varphi$. A system $\mathcal{S}$ of set constraints is satisfiable if there is a set assignment $\sigma$ that satisfies all the constraints in $\mathcal{S}$; in this case we write $\sigma \models \mathcal{S}$. We write $\mathcal{S} \vDash \varphi$ if all set assignments that satisfy $\mathcal{S}$ also satisfy $\varphi$. The satisfiability problem is to determine whether a given finite system $\mathcal{S}$ of set constraints over $\Sigma$ is satisfiable.

A truth assignment is a map $u: X \rightarrow \mathbf{2}$ where $\mathbf{2}=\{0,1\}$ is the twoelement Boolean algebra. Any truth assignment $u$ extends uniquely to a Bhomomorphism $u: T_{\mathrm{B}}(X) \rightarrow \mathbf{2}$ inductively according to the rules of Boolean algebra. If $X=\left\{x_{1}, \ldots, x_{m}\right\}$, we use the notation

$$
B\left[x_{i}:=a_{i}\right]
$$

to denote the truth value of the Boolean formula $B$ under the truth assignment $x_{i} \mapsto a_{i}, 1 \leq i \leq m$.

## 3 Expressibility

Systems of mixed positive and negative constraints are strictly more expressive than systems of positive constraints alone. We will prove this as a corollary of a general compactness theorem for positive constraints.

Theorem 1 (Compactness) A system $\mathcal{S}$ of positive set constraints is satisfiable if and only if all finite subsets of $\mathcal{S}$ are satisfiable.

Proof. The implication $(\Rightarrow)$ is straightforward. For the other direction, suppose $\mathcal{S}$ is finitely satisfiable. We wish to construct a satisfying set assignment for $\mathcal{S}$. By Zorn's Lemma, there exists a maximal finitely satisfiable set $\hat{\mathcal{S}}$ of positive constraints containing $\mathcal{S}$. One can show that for all ground terms $t$ and set expressions $E$, exactly one of the constraints $t \subseteq E, t \subseteq \sim E$ is in $\widehat{\mathcal{S}}$; if neither is in $\widehat{\mathcal{S}}$, then $\widehat{\mathcal{S}}$ is not maximal, and if both are, then $\hat{\mathcal{S}}$ is not finitely satisfiable. Now define a map

$$
\sigma(E)=\{t \mid t \subseteq E \in \hat{\mathcal{S}}\}
$$

One can show by induction on the structure of set expressions that $\sigma$ is a valid set assignment and satisfies $\hat{\mathcal{S}}$. For example, to show that

$$
\sigma\left(f E_{1} \ldots E_{n}\right)=\left\{f t_{1} \ldots t_{n} \mid t_{i} \in \sigma\left(E_{i}\right), 1 \leq i \leq n\right\},
$$

note

$$
\begin{equation*}
t \in \sigma\left(f E_{1} \ldots E_{n}\right) \Longleftrightarrow t \subseteq f E_{1} \ldots E_{n} \in \hat{\mathcal{S}} . \tag{3.1}
\end{equation*}
$$

Then $t$ must be of the form $f t_{1} \ldots t_{n}$, otherwise $\hat{\mathcal{S}}$ would not be finitely satisfiable. Now we use the fact that

$$
\begin{aligned}
f t_{1} \ldots t_{n} \subseteq f E_{1} \ldots E_{n} & \models t_{i} \subseteq E_{i}, \quad 1 \leq i \leq n \\
\left\{t_{i} \subseteq E_{i} \mid 1 \leq i \leq n\right\} & \models f t_{1} \ldots t_{n} \subseteq f E_{1} \ldots E_{n}
\end{aligned}
$$

to argue that $t \subseteq f E_{1} \ldots E_{n} \in \hat{\mathcal{S}}$ iff $t_{i} \subseteq E_{i} \in \hat{\mathcal{S}}, 1 \leq i \leq n$, otherwise $\hat{\mathcal{S}}$ would not be finitely satisfiable. Combining this with (3.1) and using the induction hypothesis, we get

$$
t \in \sigma\left(f E_{1} \ldots E_{n}\right) \Longleftrightarrow t_{i} \in \sigma\left(E_{i}\right), \quad 1 \leq i \leq n
$$

To show that $\sigma$ satisfies all constraints of $\hat{\mathcal{S}}$, let $E \subseteq F$ be any constraint in $\hat{\mathcal{S}}$. For any term $t$,

$$
\begin{align*}
t \in \sigma(E) & \Rightarrow t \subseteq E \in \hat{\mathcal{S}} \\
& \Rightarrow t \subseteq F \in \widehat{\mathcal{S}}  \tag{3.2}\\
& \Rightarrow t \in \sigma(F)
\end{align*}
$$

the reason for the implication (3.2) is that

$$
\{t \subseteq E, E \subseteq F\} \quad \vDash t \subseteq F
$$

and if $t \subseteq F$ were not in $\hat{\mathcal{S}}$, then $t \subseteq \sim F$ would be, and $\hat{\mathcal{S}}$ would not be finitely satisfiable.

Corollary 2 Finite systems of mixed positive and negative constraints are strictly more expressive than systems of positive constraints only.

Proof. Consider the single negative constraint $x \neq 0$ over any ranked alphabet $\Sigma$ with at least one constant and at least one symbol of higher arity. Solutions are $\sigma:\{x\} \rightarrow T_{\Sigma}$ with $\sigma(x)$ nonempty. Let $\mathcal{S}$ be any set, finite or infinite, of positive constraints over any set of variables $X$ containing $x$. We claim that it is not the case that the set

$$
\left\{\sigma(x) \mid \sigma: X \rightarrow T_{\Sigma}, \sigma \models \mathcal{S}\right\}
$$

is exactly the set of nonempty subsets of $T_{\Sigma}$.
Consider the infinite set of positive constraints

$$
\mathcal{S} \cup\left\{t \subseteq \sim x \mid t \in T_{\Sigma}\right\}
$$

Either this is satisfiable or not. If so, then there is a satisfying set assignment $\sigma$. But $t \in \sigma(\sim x)$ for all terms $t$, so $\sigma(x)=\emptyset$ and $\sigma \models \mathcal{S}$, and the claim is verified. If not, then by compactness there is a finite subset $F \subseteq T_{\Sigma}$ such that

$$
\mathcal{S} \cup\{t \subseteq \sim x \mid t \in F\}
$$

is not satisfiable. Therefore there is no solution $\sigma$ of $\mathcal{S}$ with $\sigma(x)=\{t\}$, where $t$ is any term not in $F$.

## 4 Set Constraints and Hypergraph Closure

In [1] it is shown how to transform a given system of positive set constraints into an equivalent system in a special normal form. The transformation is linear for fixed $\Sigma$. Applying this transformation to a system containing
negative constraints, we obtain the following normal form. Let $X$ be a set of variables, and for each $f \in \Sigma$, let

$$
Z_{f}=\left\{z_{i x}^{f} \mid 0 \leq i \leq \operatorname{arity}(f), x \in X\right\}
$$

be a set of variables such that the sets $X$ and $Z_{f}, f \in \Sigma$ are pairwise disjoint. A system of set constraints in normal form (with respect to $X$ and the $Z_{f}$ ) consists of

- a positive constraint $B=1, B \in T_{\mathrm{B}}(X)$
- for each $f \in \Sigma$, a positive constraint $C_{f}=1, C_{f} \in T_{\mathrm{B}}\left(Z_{f}\right)$
- positive constraints

$$
\begin{aligned}
z_{0 x}^{f} & =f \underbrace{1 \ldots 1}_{n} \cap x \\
z_{i x}^{f} & =f \underbrace{1 \ldots 1}_{i-1} x \underbrace{1 \ldots 1}_{n-i}
\end{aligned}
$$

for each $f \in \Sigma_{n}, 1 \leq i \leq n$, and $x \in X$

- a finite set of negative constraints $D \neq 0$, one for each element $D$ of a given finite set $\mathcal{D} \subseteq T_{\mathrm{B}}(X)$.

The last component is absent with positive constraints only.
We outline here the translation of [1] along with the minor modifications necessary to handle negative constraints.

1. For every occurrence of a subexpression $f E_{1} \ldots E_{n}$ in $\mathcal{S}$, let $y_{0}, y_{1}, \ldots, y_{n}$ be new variables. Replace $f E_{1} \ldots E_{n}$ by $y_{0}$ and add new constraints $y_{0}=f y_{1} \ldots y_{n}$ and $y_{i}=E_{i}, 1 \leq i \leq n$. Continue until all constraints are either purely Boolean or of the form $y_{0}=f y_{1} \ldots y_{n}$. Let $X$ be the set of all variables occurring in $\mathcal{S}$ at this point.
2. For each $f \in \Sigma_{n}$, introduce a new set of variables

$$
Z_{f}=\left\{z_{i x}^{f} \mid 0 \leq i \leq n, x \in X\right\}
$$

and add the constraints

$$
z_{0 x}^{f}=f \underbrace{1 \ldots 1}_{n} \cap x \quad z_{i x}^{f}=f \underbrace{1 \ldots 1}_{i-1} x \underbrace{1 \ldots 1}_{n-i}
$$

for all $1 \leq i \leq n$ and $x \in X$.
3. Assume without loss of generality that there is a variable $y \in X$ and constraint $y=1$ in $\mathcal{S}$. Each constraint $x=f x_{1} \ldots x_{n}$ obtained in step 1 is equivalent to the constraint

$$
x=f x_{1} \underbrace{1 \ldots 1}_{n-1} \cap f 1 x_{2} \underbrace{1 \ldots 1}_{n-2} \cap \cdots \cap f \underbrace{1 \ldots 1}_{n-1} x_{n} \cap f \underbrace{1 \ldots 1}_{n} .
$$

(The last term on the right hand side is redundant except in the case $n=0$. This was erroneously omitted in the account of [1]). This in turn is equivalent to the conjunction of constraints

$$
\begin{aligned}
& f \underbrace{1 \ldots 1}_{n} \cap x=f x_{1} \underbrace{1 \ldots 1}_{n-1} \cap f 1 x_{2} \underbrace{1 \ldots 1}_{n-2} \cap \cdots \cap f \underbrace{1 \ldots 1}_{n-1} x_{n} \cap f \underbrace{1 \ldots 1}_{n} \\
& g \underbrace{1 \ldots 1}_{m} \cap x=0, g \neq f, m=\operatorname{arity}(g) .
\end{aligned}
$$

Replace the constraint $x=f x_{1} \ldots x_{n}$ with the constraints

$$
z_{0 x}^{f}=\bigcap_{i=1}^{n} z_{i x_{i}}^{f} \cap z_{0, y}^{f} \quad z_{0, x}^{g}=0, g \neq f
$$

Because of the constraints introduced in step 2, the resulting system is equivalent.
4. At this point we have

- positive and negative Boolean constraints formed in step 1 involving only the variables $X$
- for each $f \in \Sigma$, positive Boolean constraints formed in step 3 involving only the variables $Z_{f}$
- mixed constraints formed in step 2.

Replace each positive Boolean constraint $E \subseteq F$ involving variables in $X$ by the equivalent constraint $\sim E \cup F=1$. Let $B$ be the conjunction of all the left hand sides of such constraints, and replace all these constraints in $\mathcal{S}$ with the single constraint $B=1$. Do the same for the purely Boolean constraints involving the variables $Z_{f}$ to get a single constraint $C_{f}=1$ for each $f \in \Sigma$. Finally, replace each negative Boolean constraint $E \not \subset F$ by the equivalent constraint $E \cap \sim F \neq 0$, and let $\mathcal{D}$ be the set of all such negative constraints.

As described in [1], a system of set constraints $\mathcal{S}$ in normal form determines a hypergraph

$$
H=\left(U, E_{f} \mid f \in \Sigma\right)
$$

as follows. The vertex set $U$ is the set of all truth assignments $u: X \rightarrow \mathbf{2}$ satisfying $B$. Each such truth assignment corresponds to a conjunction of literals (also denoted $u$ ) in which each variable in $X$ occurs exactly once, either positively or negatively, such that $u \subseteq B$ tautologically. The variable $x$ occurs positively iff $u(x)=1$. We often call the elements of $U$ atoms because they represent atoms (minimal nonzero elements) of the free Boolean algebra on generators $X$ modulo $B=1$, where "minimal" is in the sense of the natural order on the Boolean algebra. It follows from elementary Boolean algebra that each Boolean expression over $X$ is equivalent modulo $B=1$ to a disjunction of atoms.

For each $f \in \Sigma_{n}$, the hyperedge relation $E_{f}$ of $H$ is defined to be the set of all $(n+1)$-tuples $\left(u_{0}, \ldots, u_{n}\right) \in U^{n+1}$ such that

$$
\begin{equation*}
C_{f}\left[z_{i x}^{f}:=u_{i}(x)\right]=1 \tag{4.3}
\end{equation*}
$$

Intuitively, we think of the formula $C_{f}$ as a Boolean-valued mapping on $(n+1)$-tuples of truth assignments to $X$. To emphasize this intuition, we abbreviate the left hand side of (4.3) by

$$
C_{f}\left[u_{0}, \ldots, u_{n}\right] .
$$

Thus

$$
\left(u_{0}, \ldots, u_{n}\right) \in E_{f} \quad \text { iff } \quad C_{f}\left[u_{0}, \ldots, u_{n}\right]=1
$$

In general, the size of $H$ can be exponential in the size of $\mathcal{S}$.
An $(n+1)$-ary hyperedge relation $E_{f}$ of the hypergraph $H$ is said to be closed if for each $n$-tuple $u_{1}, \ldots, u_{n} \in U^{n}$, there exists $u_{0} \in U$ such that $\left(u_{0}, u_{1}, \ldots, u_{n}\right) \in E_{f}$. In the case $n=0$, this definition just says $E_{f} \cap U \neq \emptyset$. Abusing notation, we can think of $E_{f}$ as a function

$$
E_{f}: U^{n} \rightarrow 2^{U}
$$

where

$$
E_{f}\left(u_{1}, \ldots, u_{n}\right)=\left\{u_{0} \mid\left(u_{0}, u_{1}, \ldots, u_{n}\right) \in E_{f}\right\}
$$

In this view, $E_{f}$ is closed iff $E_{f}\left(u_{1}, \ldots, u_{n}\right) \neq \emptyset$ for each $n$-tuple $u_{1}, \ldots, u_{n} \in$ $U^{n}$. The hypergraph $H$ is said to be closed if all its hyperedge relations are closed.

The induced subhypergraph of $H$ on vertices $U^{\prime} \subseteq U$ is the hypergraph

$$
H^{\prime}=\left(U^{\prime}, E_{f}^{\prime} \mid f \in \Sigma\right)
$$

such that $E_{f}^{\prime}=E_{f} \cap\left(U^{\prime}\right)^{n+1}$ for $f \in \Sigma_{n}$.
The hypergraph closure problem is the problem of determining whether a given hypergraph $H$ has a closed induced subhypergraph.

The following theorem was proved in [1].
Theorem 3 The hypergraph $H$ corresponding to a system $\mathcal{S}$ of positive set constraints has a closed induced subhypergraph if and only if $\mathcal{S}$ is satisfiable.

In brief, the proof of [1] establishes a one-to-one correspondence between set assignments $\sigma$ satisfying $\mathcal{S}$ and maps $\theta: T_{\Sigma} \rightarrow U$ such that for all $f \in \Sigma$ and for all terms $f t_{1} \ldots t_{n}$,

$$
\begin{equation*}
\theta\left(f t_{1} \ldots t_{n}\right) \in E_{f}\left(\theta\left(t_{1}\right), \ldots, \theta\left(t_{n}\right)\right) \tag{4.4}
\end{equation*}
$$

The set assignment corresponding to $\theta$ is

$$
\begin{aligned}
\sigma(x) & =\{t \mid \theta(t)(x)=1\} \\
\sigma\left(z_{i x}^{f}\right) & =\sigma(f \underbrace{1 \ldots 1}_{i-1} x \underbrace{1 \ldots 1}_{n-i}) \\
\sigma\left(z_{0 x}^{f}\right) & =\sigma(f \underbrace{1 \ldots 1}_{n} \cap x) .
\end{aligned}
$$

Thus deciding the satisfiability of $\mathcal{S}$ is tantamount to determining the existence of a map $\theta$ satisfying (4.4). In turn, this is equivalent to the hypergraph closure problem: if such a $\theta$ exists, then the induced subhypergraph of $H$ on the image of $\theta$ is closed, and conversely, if there exists a closed induced subhypergraph on vertices $U^{\prime} \subseteq U$, then one can inductively define $\theta\left(f t_{1} \ldots t_{n}\right)$ to be the lexicographically first element of $U^{\prime} \cap E_{f}\left(\theta\left(t_{1}\right), \ldots, \theta\left(t_{n}\right)\right)$.

In the presence of negative constraints $D \neq 0, D \in \mathcal{D}$, the map $\theta$ must not only satisfy (4.4), but must also take on some value $u$ such that $u(D)=1$ for each $D \in \mathcal{D}$. Thus in the presence of negative constraints, the satisfiability problem becomes:

Problem 4 Given a finite set $\mathcal{D}$ of Boolean formulas $D \in T_{\mathrm{B}}(X)$ and a hypergraph $H=\left(U, E_{f} \mid f \in \Sigma\right)$ specified by $B \in T_{\mathrm{B}}(X)$ and $C_{f} \in T_{\mathrm{B}}\left(Z_{f}\right)$, $f \in \Sigma$, determine whether there exists a map $\theta: T_{\Sigma} \rightarrow U$ satisfying (4.4) such that

$$
\begin{equation*}
\text { for each } D \in \mathcal{D} \text { there exists an atom } u \text { in } \theta\left(T_{\Sigma}\right) \text { satisfying } D \text {, } \tag{4.5}
\end{equation*}
$$

where $\theta\left(T_{\Sigma}\right)$ denotes the image of $T_{\Sigma}$ under the map $\theta$.

## 5 A Reachability Problem

Our decision procedure first reduces the satisfiability problem for mixed systems of positive and negative set constraints to a certain reachability problem involving Diophantine inequalities. In this section we define the reachability problem and give the reduction.

First we describe the reachability problem on an intuitive level. Let $X$ be a set of variables ranging over $\mathbb{N}$, the natural numbers. Suppose we are given a finite system $C$ of formal inequalities $p \leq q$, where $p$ and $q$ are polynomials in the variables $X$ with coefficients in $\mathbb{N}$, such that

- each left hand side $p$ is a sum of variables in $X$
- each variable occurs in at most one left hand side.

An assignment is a map $u: X \rightarrow \mathbb{N}$. Each assignment $u$ extends uniquely to an evaluation morphism $u: \mathbb{N}[X] \rightarrow \mathbb{N}$ which evaluates polynomials at $u$. A variable $x$ is said to be enabled under an assignment $u$ if either

- the variable $x$ does not occur on the left hand side of any constraint in $C$; or
- the unique constraint in $C$ in which $x$ appears on the left hand side is a strict inequality under the assignment $u$.

Consider the following nondeterministic procedure. Starting with the zero assignment, repeatedly choose a variable that is enabled and "fire" it by incrementing it by 1 . The reachability problem is to decide whether there exists a sequence of legal firings that allows a particular distinguished variable to be fired.

We give a more rigorous presentation of this problem below, then reduce the satisfiability problem to this problem. In Section 6 we show that the reachability problem is decidable.

### 5.1 Polynomials and Assignments

We use the term ring to mean commutative ring with unit and semiring to mean commutative semiring with unit.

Let $\mathbb{Z}$ denote the ring of integers and $\mathbb{N} \subseteq \mathbb{Z}$ the semiring of natural numbers with the usual addition and multiplication operations. For $X$ a finite set of variables, let $\mathbb{Z}[X]$ denote the ring of polynomials in the variables $X$ with integer coefficients and $\mathbb{N}[X] \subseteq \mathbb{Z}[X]$ the semiring of polynomials with positive coefficients. The ring $\mathbb{Z}[X]$ is the free ring on generators $X$ and the semiring $\mathbb{N}[X]$ is the free semiring on generators $X$.

Any map $u: X \rightarrow R$ to a ring $R$ extends uniquely to a ring homomorphism $u: \mathbb{Z}[X] \rightarrow R$. If $S$ is a semiring and $S \subseteq R$, and if $u(x) \in S$ for $x \in X$, then the restriction of $u: \mathbb{Z}[X] \rightarrow R$ to domain $\mathbb{N}[X]$ is a semiring homomorphism $\mathbb{N}[X] \rightarrow S$, and is the unique semiring homomorphism extending $u: X \rightarrow S$. We will concentrate on the case $S=\mathbb{N}$ and $R=\mathbb{Z}$; we call such a map an assignment. However, functional composition of polynomials is effected by the same construction with $S=\mathbb{N}[X]$ and $R=\mathbb{Z}[X]$.

Intuitively, an assignment $u: X \rightarrow \mathbb{N}$ should be regarded as an assignment of values to the variables, and $u(q)$ the result of evaluating the polynomial $q$ on those values.

The set of assignments, considered as functions of $X$, forms a commutative monoid $\mathcal{V}$ under pointwise addition $u+v: x \mapsto u(x)+v(x), x \in X$, with identity element the zero assignment $0: x \mapsto 0, x \in X$. The monoid $\mathcal{V}$ is isomorphic to the commutative monoid $\mathbb{N}^{|X|}$ with ordinary addition under the map $v \mapsto(v(x) \mid x \in X)$.

Care must be taken here: it is not the case that $(u+v)(q)=u(q)+v(q)$ for $q \in \mathbb{Z}[X]$ in general. The value of $(u+v)(q)$ is governed by the definition of the unique extension of assignments to homomorphisms. For example,

$$
(u+v)(x+1)=(u+v)(x)+(u+v)(1)=u(x)+v(x)+1,
$$

whereas

$$
u(x+1)+v(x+1)=u(x)+v(x)+2
$$

However, we do have the following useful inequality:
Lemma 5 For any $q \in \mathbb{N}[X]$,

$$
(u+v)(q) \geq u(q)+v(q)-\mathbf{0}(q)
$$

with equality holding if $q$ is affine (i.e., linear plus a constant term).
Proof. This can be proved by induction on the form of $q$. Note that $\mathbf{0}(q)$ is the constant term of $q$. For $x \in X$, we have $(u+v)(x)=u(x)+v(x)$, and for constants $a \in \mathbb{N},(u+v)(a)=a=u(a)+v(a)-\mathbf{0}(a)$. For polynomials of the form $p q$ where neither $p$ nor $q$ has a constant term,

$$
\begin{aligned}
(u+v)(p q) & =(u+v)(p) \cdot(u+v)(q) \\
& \geq(u(p)+v(p)) \cdot(u(q)+v(q)) \\
& \geq u(p) \cdot u(q)+v(p) \cdot v(q) \\
& =u(p q)+v(p q)
\end{aligned}
$$

Finally, for polynomials of the form $p+q$,

$$
\begin{aligned}
(u+v)(p+q) & =(u+v)(p)+(u+v)(q) \\
& \geq u(p)+v(p)-\mathbf{0}(p)+u(q)+v(q)-\mathbf{0}(q) \\
& =u(p+q)+v(p+q)-\mathbf{0}(p+q)
\end{aligned}
$$

with equality holding if $p$ and $q$ are affine, by the induction hypothesis.
In particular, $(u+v)(q)=u(q)+v(q)$ if $q$ is linear with constant coefficient 0 .

For $v: X \rightarrow \mathbb{N}$ an assignment, let inc $\boldsymbol{c}_{v}: \mathbb{Z}[X] \rightarrow \mathbb{Z}[X]$ be the unique ring homomorphism such that

$$
\operatorname{inc}_{v}(x)=x+v(x), \quad x \in X .
$$

Informally, $\operatorname{inc}_{v}(p)$ is the polynomial obtained from $p$ by substituting $x+v(x)$ for $x$. Intuitively, $\operatorname{inc}_{v}$ says, "Automatically increase the value of $x \in X$ by $v(x)$." Restricted to domain $\mathbb{N}[X]$, inc $c_{v}$ is a semiring homomorphism $\mathbb{N}[X] \rightarrow \mathbb{N}[X]$, for which we use the same name.

The homomorphism $\operatorname{inc}_{v}$ is the unique map such that the diagram

commutes, i.e. such that $u \circ \operatorname{inc}_{v}=u+v$ : for $x \in X$,

$$
\begin{align*}
(u+v)(x) & =u(x)+v(x) \\
& =u(x+v(x))  \tag{5.7}\\
& =u\left(\operatorname{inc}_{v}(x)\right) .
\end{align*}
$$

Equation (5.7) holds since $v(x)$ is a constant. Since the homomorphisms $u+v$ and $u \circ \mathbf{i n c}_{v}$ agree on $X$, they agree everywhere. The homomorphism inc $v_{v}$ is unique, since it is determined by its values on $x \in X$, and the polynomial $\operatorname{inc}_{v}(x)$ is determined by its set of values $u\left(\operatorname{inc}_{v}(x)\right)=u(x)+v(x)$.

By composing two copies of (5.6), one observes that the set

$$
\mathcal{I}=\left\{\text { inc }_{v} \mid v \text { an assignment }\right\}
$$

forms a monoid under functional composition o with identity inc. $\mathbf{c}_{\mathbf{0}}$. Moreover, $\mathcal{I}$ is isomorphic to the monoid of assignments $\mathcal{V}$ under the map $v \mapsto$ inc $_{v}$; i.e.,

$$
\operatorname{inc}_{u+v}=\text { inc }_{u} \circ \text { inc }_{v} .
$$

The map $v \mapsto$ inc $_{v}$ is bijective, since $v$ can be recovered uniquely from inc ${ }_{v}$ by taking $u=\mathbf{0}$ in (5.7).

It follows immediately that $\mathrm{inc}_{u}$ and $\mathrm{inc}_{v}$ commute under composition, i.e. inc $_{u} \circ$ inc $_{v}=$ inc $_{v} \circ$ inc $_{u}$.

One application of particular importance will be incrementing the value of a variable $x$ under an assignment $u$ by 1 . The new assignment is $u+\delta_{x}$, where $\delta_{x}(x)=1$ and $\delta_{x}(y)=0$ for $y \neq x$. The effect of applying inc $\boldsymbol{\delta}_{\delta_{x}}$ to a polynomial $q$ is the same as substituting $x+1$ for $x$ in $q$.

Let $X^{*}$ denote the monoid of finite-length strings over $X$. This is the free monoid on generators $X$. Elements of $X^{*}$ will be denoted $\sigma, \tau, \rho, \ldots$

There is a unique monoid homomorphism $\llbracket \rrbracket: X^{*} \rightarrow \mathcal{V}$ extending the map $x \rightarrow \delta_{x}, x \in X$. The image of $\sigma=x_{1} \cdots x_{n}$ under this map is $\llbracket \sigma \rrbracket=$
$\sum_{i=1}^{n} \delta_{x_{i}}$. Applied to $x$, the function $\llbracket \sigma \rrbracket$ gives the number of occurrences of $x$ in the string $\sigma$. This is known in formal language theory as the Parikh map. By a slight abuse of notation, we omit the braces $\llbracket \rrbracket$ when using $\llbracket \sigma \rrbracket$ as a function; thus $\sigma(x)$ denotes the number of occurrences of $x$ in $\sigma$, and $\sigma(q)$ is the value of the polynomial $q$ under the assignment $\llbracket \sigma \rrbracket$.

### 5.2 Systems of Diophantine Inequalities

We consider finite systems $C$ of Diophantine inequalities of the form $p \leq q$ where $p, q \in \mathbb{N}[X]$ such that

- each left hand side $p$ is a sum of distinct variables; and
- each variable in $X$ occurs in at most one left hand side.

There is no restriction on the form of the right hand sides $q$ except that they be in $\mathbb{N}[X]$. The inequalities in $C$ are called (Diophantine) constraints. A variable $x \in X$ is said to be constrained in $C$ if $x$ occurs on the left hand side of some constraint in $C$. In this case we denote the unique such constraint by con $(x, C)$. If $x$ does not occur on the left hand side of any constraint in $C$, then $x$ is said to be unconstrained in $C$, and we write $\operatorname{con}(x, C)=*$.

We say that the assignment $u$ satisfies the constraint $p \leq q$ if $u(p) \leq u(q)$. We say that $u$ satisfies $C$ if $u$ satisfies all the constraints in $C$. We say that $\sigma \in X^{*}$ satisfies a constraint or set of constraints if $\llbracket \sigma \rrbracket$ does.

### 5.3 The Nonlinear Reachability Problem

Let $C$ be a system of Diophantine constraints as described above and let $x_{0} \in X$ be a fixed distinguished variable.

Definition 6 Let $\sigma \in X^{*}$. The constraint $p \leq q \in C$ is said to be $\sigma$-enabled if $\sigma(p)<\sigma(q)$; i.e., the inequality is strict under the assignment $\llbracket \sigma \rrbracket$. The variable $x \in X$ is said to be ( $\sigma, C$ )-enabled if either

- $x$ is unconstrained in $C$, or
- $x$ is constrained in $C$ and $\operatorname{con}(x, C)$ is $\sigma$-enabled.

A tree, for our purposes, is a nonempty prefix-closed subset $T$ of $X^{*}$. The root of $T$ is $\epsilon$. The parent of $\sigma \neq \epsilon$ is the longest proper prefix of $\sigma$. A leaf of $T$ is an element of $T$ that is not a parent. A path of $T$ is a maximal subset of $T$ linearly ordered by the prefix relation.

The system $C$ gives rise to a tree

$$
T_{C}=\left\{\sigma \in X^{*} \mid \text { for all prefixes } \tau x \text { of } \sigma, x \text { is }(\tau, C) \text {-enabled. }\right\}
$$

The tree $T_{C}$ describes the possible legal sequences of firings that can take place according to the informal description of the nonlinear reachability problem given in Section 5.

Definition 7 The Nonlinear Reachability Problem (NRP) is to determine, given $C$, whether $T_{C}$ contains an element $\sigma$ such that $\sigma\left(x_{0}\right)>0$. Such a $\sigma$ is called a solution of the given instance $C$ of the NRP.

In other words, determine whether there exists a legal firing sequence such that the distinguished variable $x_{0}$ is fired.

Note that $\epsilon$ satisfies $C$ since $\llbracket \epsilon \rrbracket=\mathbf{0}$, and if $\sigma$ satisfies $C$ and $x$ is $(\sigma, C)$ enabled, then $\sigma x$ satisfies $C$, since $\llbracket \sigma x \rrbracket=\llbracket \sigma \rrbracket+\delta_{x}$. It follows by induction that $\sigma$ satisfies $C$ for every $\sigma \in T_{C}$. In other words, if $\sigma$ satisfies $C$ and $x$ is ( $\sigma, C$ )-enabled, then we can fire $x$ and the resulting assignment still satisfies $C$. The converse is false in general; i.e., it is possible that both $\sigma$ and $\sigma x$ satisfy $C$ but $x$ is not ( $\sigma, C$ )-enabled: consider the constraint $x \leq x$.

### 5.4 Reduction of Set Constraint Satisfiability to Nonlinear Reachability

Theorem 8 The satisfiability problem for systems of mixed positive and negative set constraints reduces effectively to a finite disjunction of instances of the Nonlinear Reachability Problem.

Proof. As argued in Section 4, the satisfiability problem for systems of mixed positive and negative constraints is equivalent to Problem 4. Using the notation of Problem 4, let $\mathcal{U}$ be the set of all subsets $V \subseteq U$ such that for all $D \in \mathcal{D}$ there exists a $v \in V$ with $v(D)=1$. Consider a modified version of Problem 4 in which condition (4.5) is replaced by the condition

$$
\begin{equation*}
V \subseteq \theta\left(T_{\Sigma}\right) \tag{5.8}
\end{equation*}
$$

Then Problem 4 is equivalent to the disjunction over all $V \in \mathcal{U}$ of instances of the modified version. Furthermore, we will only need to construct a finite partial approximation $\theta^{\prime}$ to $\theta$ satisfying (4.4) and (5.8), provided

- the domain of $\theta^{\prime}$ is closed downward under the subterm relation
- there is a closed induced subhypergraph of $H$ containing the image of $\theta^{\prime}$.

The second property will allow $\theta^{\prime}$ to be completed to a total function $\theta$, as described below.

Thus the problem now becomes:
Problem 9 Given a hypergraph $H=\left(U, E_{f} \mid f \in \Sigma\right)$ specified by $B$ and $C_{f}, f \in \Sigma$, and a subset $V \subseteq U$, determine whether there exist $U^{\prime} \subseteq U$ and a partial map $\theta: T_{\Sigma} \rightarrow U^{\prime}$ with finite domain such that

- the induced subhypergraph on $U^{\prime}$ is closed
- the domain of $\theta$ is closed downward under the subterm relation
- $\theta$ satisfies (4.4) on all terms in its domain
- $V \subseteq \theta\left(T_{\Sigma}\right) \subseteq U^{\prime}$.

Consider the following nondeterministic procedure for constructing $\theta$. We first guess the subset $U^{\prime}$ containing the target set $V$ and check that it is closed. We start with $\theta$ totally undefined. At any point, say we have a partial $\theta$ with finite domain closed downward under the subterm relation. We nondeterministically pick some term $f t_{1} \ldots t_{n}$ such that the $\theta\left(t_{i}\right)$ are defined but $\theta\left(f t_{1} \ldots t_{n}\right)$ is not yet defined, nondeterministically choose some $u$ in $E_{f}\left(\theta\left(t_{1}\right), \ldots, \theta\left(t_{n}\right)\right) \cap U^{\prime}$, and assign $\theta\left(f t_{1} \ldots t_{n}\right):=u$. We are always able to continue, since $U^{\prime}$ is closed. We halt successfully when and if all elements of $V$ have been chosen as $\theta(t)$ for some $t$.

During this process, we use an integer variable $x_{u, f, u_{1}, \ldots, u_{n}}, n=\boldsymbol{\operatorname { a r i t y }}(f)$, to count the number of terms of the form $f t_{1} \ldots t_{n}$ such that

- $\theta\left(t_{i}\right)$ exists and equals $u_{i}, 1 \leq i \leq n$, and
- $\theta\left(f t_{1} \ldots t_{n}\right)$ exists and equals $u$.

There is one such variable for each choice of $f$ in $\Sigma, u_{1}, \ldots, u_{n} \in U^{\prime}$ where $n=\operatorname{arity}(f)$, and $u \in U^{\prime} \cap E_{f}\left(u_{1}, \ldots, u_{n}\right)$.

Now for each $f \in \Sigma_{n}$ and $u_{1}, \ldots, u_{n} \in U^{\prime}$, consider the formal inequality

$$
\begin{equation*}
\sum_{u \in U^{\prime} \cap E_{f}\left(u_{1}, \ldots, u_{n}\right)} x_{u, f, u_{1}, \ldots, u_{n}} \leq \prod_{i=1}^{n} \sum_{m=0}^{M} \sum_{\substack{v_{1}, \ldots, v_{m} \in U^{\prime} \\ g \in \Sigma_{m}}} x_{u_{i}, g, v_{1}, \ldots, v_{m}} \tag{5.9}
\end{equation*}
$$

where $M$ is the maximum arity of symbols in $\Sigma$. This inequality has the following significance. Given a partial map $\theta$, let

$$
\begin{aligned}
B_{u} & =\{t \mid \theta(t) \text { exists and equals } u\} \\
A_{f, u_{1}, \ldots, u_{n}} & =\left\{f t_{1} \ldots t_{n} \mid t_{i} \in B_{u_{i}}, 1 \leq i \leq n\right\} .
\end{aligned}
$$

The value of the right hand side of (5.9) is the size of $A_{f, u_{1}, \ldots, u_{n}}$, which is the the size of the direct product $B_{u_{1}} \times \cdots \times B_{u_{n}}$. The value of the left hand side of (5.9) is the size of the subset of $A_{f, u_{1}, \ldots, u_{n}}$ consisting of all elements $t$ for which $\theta(t)$ is defined. The inequality expresses the fact that $\theta$ is defined on the subterms of $t$ before being defined on $t$.

Consider the collection $C$ of all such inequalities (5.9). To say that a variable $x_{u, f, u_{1}, \ldots, u_{n}}$ is enabled says that there exists a term $t$ with head symbol $f$ such that $\theta$ is defined on the $n$ immediate subterms and takes values $u_{1}, \ldots, u_{n}$ on those subterms respectively, but $\theta(t)$ is not yet defined. To fire $x_{u, f, u_{1}, \ldots, u_{n}}$ says that we choose one such $t$ and define $\theta(t):=u$.

The process of defining $\theta$ from the bottom up as described above corresponds to a sequence of legal firings. Conversely, any legal sequence of firings gives a corresponding sequence of definitions of $\theta$ starting with the totally undefined map.

We have thus reduced the satisfiability problem for systems of mixed positive and negative set constraints to a disjunction of instances of the problem of determining, given $C$ and $V$, whether there is a finite sequence of legal firings after which for all $v \in V$ there are $f$ and $u_{1}, \ldots, u_{n}$ such that the value of $x_{v, f, u_{1}, \ldots, u_{n}}$ is nonzero.

We reduce this problem to a finite disjunction of instances of the NRP as follows. For each $v \in V$, choose $f$ and $u_{1}, \ldots, u_{n}$ and let $y_{v}=x_{v, f, u_{1}, \ldots, u_{n}}$. Add the constraint

$$
x_{0} \leq \prod_{v \in V} y_{v}
$$

where $x_{0}$ is a new variable, and make $x_{0}$ the distinguished variable of the NRP so obtained. The variable $x_{0}$ can be fired only after all the $y_{v}$ have been fired. The problem above is equivalent to the disjunction of all such instances of the NRP over all possible choices of the $y_{v}$.

## 6 Decidability of the Nonlinear Reachability Problem

In this section we prove the decidability of the NRP. We will start by defining several technical concepts on which our proof is based and deriving their basic properties. The most important of these concepts are the notions of exposed and inhibited variables and admissible strings. Intuitively, a variable is exposed in a polynomial $q$ if incrementing it causes the value of $q$ to increase. The intuition behind the definition inhibited variable is that it does no good to increment such a variable under the current state of affairs. A string $\sigma$ is admissible if it never increments any inhibited variable. We show that if there exists a solution, then there exists an admissible one. The final argument shows that if we construct the tree $T_{C}$ breadth-first, ignoring nonadmissible strings, then along any path we will eventually encounter either a solution, a leaf with no admissible extensions, or a configuration that allows us to reduce the size of the system.

### 6.1 Reset

We first describe a useful technical device called a reset. Intuitively, after executing a firing sequence $\sigma$ that is legal with respect to a set of constraints $C$, we can construct a new instance of the problem $\operatorname{inc}_{\sigma}(C)$ (defined below) which allows us to proceed as if we were starting afresh.

Definition 10 Let $C$ be a system of Diophantine constraints as defined in Section 5.2. If $\sigma \in T_{C}$, we define $T_{C}^{\sigma}$ to be the subtree of $T_{C}$ rooted at $\sigma$ :

$$
T_{C}^{\sigma}=\left\{\tau \in X^{*} \mid \sigma \tau \in T_{C}\right\} .
$$

This set is nonempty and prefix-closed, therefore a tree.

Note that $\llbracket \sigma \rrbracket$ alone determines whether a variable is $\sigma$-enabled. It follows inductively that if $\sigma, \tau \in T_{C}$ and $\llbracket \sigma \rrbracket=\llbracket \tau \rrbracket$, then $T_{C}^{\sigma}=T_{C}^{\tau}$.

Let $v$ be any assignment satisfying $C$, and let inc $_{v}$ be as in Section 5.1. Let inc $v_{v}(C)$ denote the system of constraints

$$
\operatorname{inc}_{v}(C)=\left\{p \leq \operatorname{inc}_{v}(q)-v(p) \mid p \leq q \in C\right\} .
$$

The right hand sides $\operatorname{inc}_{v}(q)-v(p)$ are in $\mathbb{N}[X]$, since the constant coefficient of $\operatorname{inc}_{v}(q)$ is at least $v(p)$. This is a consequence of the fact that $v$ satisfies $C$ :

$$
v(p) \leq v(q)=\mathbf{0}\left(\operatorname{inc}_{v}(q)\right)
$$

Moreover, $x$ is constrained in $C$ iff it is constrained in inc $\boldsymbol{c}_{v}(C)$, since all the left hand sides are the same.

Note also that the constraint $p \leq \operatorname{inc}_{v}(q)-v(p) \in \operatorname{inc}_{v}(C)$ is equivalent to $\operatorname{inc}_{v}(p) \leq \operatorname{inc}_{v}(q)$, since $\operatorname{inc}_{v}(p)=p+v(p)$ for $p$ a sum of variables.

Lemma 11 Let $C$ be a set of constraints and $\sigma \in T_{C}$. Then

$$
T_{C}^{\sigma}=T_{\mathbf{i n c}_{\sigma}(C)}
$$

Proof. Certainly $\epsilon$ is a member of both trees. Moreover, for any constraint $p \leq q \in C$, we have from (5.6) that

$$
\tau\left(\operatorname{inc}_{\sigma}(q-p)\right)=\sigma \tau(q-p)
$$

and $\operatorname{con}(x, C)=\boldsymbol{\operatorname { c o n }}\left(x, \operatorname{inc}_{\sigma}(C)\right)$, thus $x$ is $\left(\tau, \operatorname{inc}_{\sigma}(C)\right)$-enabled iff $x$ is $(\sigma \tau, C)$-enabled. Thus the trees are identical.

### 6.2 Order

Our algorithm will construct part of the tree $T_{C}$. During this construction, we will want to keep track of the values of $q-p$ for $p \leq q \in C$, since this information will help us determine when we have reached a situation in which progress has been made. We define the order $\leq_{C}$ for this purpose. We also define the order $\leq_{x}$, which is just the natural order on the set of assignments.

Definition 12 For $C$ a system of constraints and $\sigma, \tau \in X^{*}$, define

- $\sigma \leq_{X} \tau$ if $\sigma(x) \leq \tau(x)$ for all $x \in X$
- $\sigma \leq_{C} \tau$ if $\sigma(q-p) \leq \tau(q-p)$ for all $p \leq q \in C$
- $\sigma \leq_{X, C} \tau$ if both $\sigma \leq_{X} \tau$ and $\sigma \leq_{C} \tau$
- $\sigma \equiv_{C} \tau$ if both $\sigma \leq_{C} \tau$ and $\tau \leq_{C} \sigma$.

It follows from Lemma 5 and the observation that $\mathbf{0}(q)$ is the constant coefficient of $q$ that for $q \in \mathbb{N}[X]$, if $\sigma \leq_{X} \tau$ then $\sigma(q) \leq \tau(q)$.

Note that the relations $\leq_{X}$ and $\leq_{C}$ depend only on the assignments $\llbracket \sigma \rrbracket$ and not on the strings $\sigma$ themselves. Note also that if $\sigma \tau \in T_{C}$ then $\sigma \leq_{X} \sigma \tau$. The same statement is not true in general for $\leq_{C}$; for example, take $\sigma=\epsilon$, $\tau=x$, and $C=\{x \leq y+1\}$.

Lemma 13 Let $x \in X, \sigma, \tau \in X^{*}$ such that $\sigma \leq_{X} \tau$, and $p \leq q \in C$. Then

$$
\sigma x(q-p)-\sigma(q-p) \leq \tau x(q-p)-\tau(q-p) .
$$

Proof. Using Lemma 5 and the facts that $\llbracket \sigma x \rrbracket=\llbracket \sigma \rrbracket+\delta_{x}$ and $p$ is linear, it follows that the inequality in the statement of the Lemma is equivalent to

$$
\sigma x(q)-\sigma(q) \leq \tau x(q)-\tau(q)
$$

By (5.6), this is equivalent to

$$
\sigma\left(\operatorname{inc}_{x}(q)-q\right) \leq \tau\left(\operatorname{inc}_{x}(q)-q\right)
$$

But this inequality follows from the assumptions of the Lemma, since $\sigma \leq_{X} \tau$ and $\operatorname{inc}_{x}(q)-q \in \mathbb{N}[X]$.

Lemma 14 Let $\sigma, \tau \in T_{C}$ and $x \in X$.
(i) If $x$ is $(\sigma, C)$-enabled and $\sigma \leq_{C} \tau$, then $x$ is $(\tau, C)$-enabled.
(ii) If $\sigma \leq_{X} \tau$ then $\sigma x \leq_{X} \tau x$.
(iii) If $\sigma \leq_{X, C} \tau$, then $\sigma x \leq_{X, C} \tau x$.

Proof. The assertions (i) and (ii) are straightforward consequences of the definitions. The assertion (iii) follows from (ii) and Lemma 13.

### 6.3 Well Partial Orders and Dickson's Lemma

A well partial order is a partially ordered set in which every infinite sequence has an infinite monotone nondecreasing subsequence. That is, for every infinite sequence $d_{0}, d_{1}, \ldots$, there exist indices $i_{0}<i_{1}<\cdots$ such that $d_{i_{0}} \leq d_{i_{1}} \leq \cdots$.

Lemma 15 (Dickson's Lemma) The set $\mathbb{N}^{k}$ of $k$-tuples of natural numbers under the componentwise order is a well partial order.

For a proof of Dickson's Lemma, see [10].
We will use Dickson's Lemma in the argument below to conclude that along any infinite path in $T_{C}$, we must eventually have $\sigma \leq_{C} \sigma \tau$. Here we are taking $k=|C|$ and comparing the $k$-tuples $(\sigma(q-p) \mid p \leq q \in C)$.

### 6.4 Exposed Variables

Intuitively, a variable $x$ is $\sigma$-exposed in a polynomial $q$ iff, after executing $\sigma$, firing $x$ would cause the value of $q$ to increase strictly. The following definition and lemma make this intuition precise.

Definition 16 Let $x \in X$ and $\sigma \in T_{C}$. We say that $x$ is $\sigma$-exposed in a monomial $q x^{i}$, where $x$ does not appear in $q$, if $i \geq 1$ and $\sigma(q) \neq 0$. For $q \in \mathbb{N}[X]$, we say that $x$ is $\sigma$-exposed in $q$ if $x$ is $\sigma$-exposed in some monomial of $q$. We say that $x$ is $(\sigma, C)$-exposed if $x$ is $\sigma$-exposed in $q$ for some $p \leq q \in C$.

Lemma 17 Let $x \in X, q \in \mathbb{N}[X]$, and $\sigma \in T_{C}$. Then $x$ is $\sigma$-exposed in $q$ iff $\sigma(q)<\sigma x(q)$.

Proof. Since $\sigma$ and $\sigma x$ are homomorphisms and all values are nonnegative, it suffices to show the result for monomials $a x^{i}, a \in \mathbb{N}[X-\{x\}]$. Since $\sigma x(a)=\sigma(a)$,

$$
\sigma x\left(a x^{i}\right)-\sigma\left(a x^{i}\right)=\sigma(a)\left((\sigma(x)+1)^{i}-\sigma(x)^{i}\right) \geq 0
$$

with equality holding iff $i=0$ or $\sigma(a)=0$.
The following lemma establishes some basic properties of the notion of exposure and its relation to enabling and the relation $\leq_{C}$.

Lemma 18 Let $x \in X, p \leq q \in C$, and $\sigma, \tau \in T_{C}$.
(i) If $x$ is $\sigma$-exposed in $q$ and $\sigma \leq_{x} \tau$, then $x$ is $\tau$-exposed in $q$ (once exposed, always exposed).
(ii) If $x$ is $\sigma$-exposed in $q$, then $\sigma x(q-p) \geq \sigma(q-p)$; moreover, if $x$ does not occur in $p$, then the inequality is strict.
(iii) If $x$ is not ( $\sigma, C$ )-exposed, then $\sigma x \leq_{C} \sigma$.
(iv) The property of exposure in the right hand side of a constraint $p \leq q \in$ $C$ is preserved under a reset. Formally, $x$ is $\sigma \tau$-exposed in $q$ iff $x$ is $\tau$-exposed in $\operatorname{inc}_{\sigma}(q)-\sigma(p)$.
(v) If $\sigma(x)>0, x$ is not $\sigma$-exposed in $q$, and $x$ is $\sigma y$-exposed in $q$, then $y$ is $\sigma$-exposed in $q$.

Proof. Except for (iv) and (v), all statements are direct consequences of Definition 16 and Lemma 17.

To prove (iv), we use (5.6) and Lemma 17:

$$
\begin{aligned}
\sigma \tau x(q)-\sigma \tau(q) & =\tau x\left(\mathbf{i n c}_{\sigma}(q)\right)-\tau\left(\mathbf{i n c}_{\sigma}(q)\right) \\
& =\tau x\left(\mathbf{i n c}_{\sigma}(q)-\sigma(p)\right)-\tau\left(\mathbf{i n c}_{\sigma}(q)-\sigma(p)\right)
\end{aligned}
$$

since $\sigma(p)$ is a constant.
For (v), there must be a monomial $a x^{i}$ of $q, i \geq 1, a \in \mathbb{N}[X-\{x\}]$, such that $\sigma(a)=0$ and $\sigma y(a)>0$. Since $\sigma y(x) \geq \sigma(x)>0$, we have $\sigma y\left(a x^{i}\right)>0=\sigma\left(a x^{i}\right)$, thus $\sigma y(q)>\sigma(q)$. By Lemma 17, $y$ is $\sigma$-exposed in $q$.

### 6.5 Inhibited Variables and Admissible Strings

The technical notion of an inhibited variable captures the idea that, under the current state of affairs, firing the variable makes no progress toward a solution. Intuitively, firing a variable makes progress only if the variable is exposed, so that firing it might enable another variable, or has value 0 , so that firing it might contribute to the exposure of another variable.

We will formalize and prove a result that says intuitively that any string $\sigma$ can be simulated by another string $\tau$ in which no inhibited variable is ever fired. Such a string $\tau$ is called admissible.

Definition 19 Let $C$ be a system of Diophantine constraints and $\sigma \in T_{C}$. We say $x \in X$ is ( $\sigma, C$ )-inhibited if

- $x$ is unconstrained in $C$,
- $x$ is not $(\sigma, C)$-exposed, and
- $\sigma(x)>0$.

We say that $\sigma \in X^{*}$ is $C$-admissible if $\sigma \in T_{C}$, and for all prefixes $\tau y$ of $\sigma$, $y$ is not $(\tau, C)$-inhibited.

Lemma 20 (i) If $y$ is $(\sigma, C)$-inhibited, then $\sigma(p)=\sigma y(p)$ and $\sigma(q)=$ $\sigma y(q)$ for all constraints $p \leq q \in C$. In particular, $\sigma y \equiv_{C} \sigma$.
(ii) If $y, z$ are $(\sigma, C)$-inhibited, then $z$ is $(\sigma y, C)$-inhibited. (This also applies to the case $y=z$.)

Proof.
(i) Since $y$ is unconstrained, it does not appear in $p$, therefore $\sigma(p)=$ $\sigma y(p)$. Since $y$ is not $\sigma$-exposed in $q$, we have $\sigma(q)=\sigma y(q)$ by Lemma 17.
(ii) Surely $\sigma y(z) \geq \sigma(z)>0$ and $z$ is still unconstrained in $C$. Since $y$ and $z$ are not $(\sigma, C)$-exposed, they are not exposed in $q$ for any $p \leq q \in C$. Since $\sigma(z)>0$, it follows from Lemma 18(v) that $z$ is not $\sigma y$-exposed in $q$. Thus $z$ is not $(\sigma y, C)$-exposed.

The following two lemmas imply that we can restrict our attention to admissible strings when looking for solutions.

Lemma 21 For every $\sigma \in T_{C}$, there exists a $C$-admissible string $\tau \in T_{C}$ such that $\sigma \leq_{C} \tau$.

Proof. Let us call a prefix $\sigma_{1} y$ of $\sigma$ bad if $y$ is $\left(\sigma_{1}, C\right)$-inhibited. The proof is by lexicographical induction on the length of $\sigma$; among strings of the same length, the number of bad prefixes; and among strings of the same length and same number of bad prefixes, the length of the longest bad prefix ("longer" is "smaller" in the induction). If $\sigma$ is null or has no bad prefix, there is nothing to prove. If the longest bad prefix $\sigma_{1} y$ is $\sigma$ itself, then since $y$ is not $\left(\sigma_{1}, C\right)$-exposed, we have by Lemma 18 (iii) that $\sigma_{1} y \leq_{C} \sigma_{1}$, and we are done by the induction hypothesis. Otherwise, there exists a $z$ and $\sigma_{2}$ such that $\sigma=\sigma_{1} y z \sigma_{2}$. Now $z$ is not ( $\sigma_{1} y, C$ )-inhibited, by the maximality of $\sigma_{1} y$. Neither is it $\left(\sigma_{1}, C\right)$-inhibited, by Lemma $20(i i)$. Moreover, $z$ is $\left(\sigma_{1}, C\right)$ enabled, by Lemma 20(i) and the fact that it is $\left(\sigma_{1} y, C\right)$-enabled, and $y$ is $\left(\sigma_{1} z, C\right)$-enabled since it is unconstrained. Therefore $\sigma_{1} z y \sigma_{2} \in T_{C}$ is of the same length as $\sigma$, but with either strictly fewer bad prefixes (if $\sigma_{1} z y$ is not a bad prefix) or the same number of bad prefixes and a strictly longer maximal one (if it is). The result follows from the induction hypothesis.

Lemma 22 If a given instance of the NRP with constraints $C$ has a solution, then it has an admissible solution.

Proof. Let $\sigma$ be a solution of minimal length. Then $\sigma$ is of the form $\tau x_{0}$ and $\tau\left(x_{0}\right)=0$. By Lemma 21, there exists an admissible $\rho$ such that $\tau \leq_{C} \rho$. If $\rho\left(x_{0}\right)>0$, then $\rho$ is the desired admissible solution. Otherwise, $x_{0}$ is $(\rho, C)$-enabled (since $\tau \leq_{C} \rho$ and $x_{0}$ is $(\tau, C)$-enabled) and not $(\rho, C)$ inhibited (since $\rho\left(x_{0}\right)=0$ ), therefore $\rho x_{0}$ is the desired admissible solution.

### 6.6 The Graphs $H(\sigma, C)$

We now describe a family of graphs $H(\sigma, C)$ defined in terms of a given system $C$ of constraints and $\sigma \in T_{C}$. The purpose of these graphs is to keep track of the exposed variables and how firing them can enable other constraints, so that we can monitor the progress of a firing sequence.

Formally, $H(\sigma, C)$ is a finite labeled directed graph with vertices $C \cup\{*\}$. For each $p \leq q \in C$ and $x \in X$ such that $x$ is $\sigma$-exposed in $q$, there is an edge labeled $x$ from $\operatorname{con}(x, C)$ to $p \leq q$. (Recall that $\operatorname{con}(x, C)$ is $*$ if $x$ is unconstrained in $C$, otherwise con $(x, C)$ is some constraint $p \leq q \in C$.) Selfloops are allowed in this definition: if $x$ is constrained in $C$ by the constraint
$p \leq q$ and $x$ is $\sigma$-exposed in $q, H(\sigma, C)$ has a self-loop labeled $x$ on the vertex $p \leq q$.

It follows from Lemma 18(i) that if $\sigma \leq_{x} \tau$ then $H(\sigma, C)$ is a subgraph of $H(\tau, C)$. In particular, $H(\sigma, C)$ is a subgraph of $H(\sigma x, C)$. Moreover, it follows from Lemma $18($ ii $)$ that if $\sigma \in T_{C}, x$ is $(\sigma, C)$-enabled, and $H(\sigma, C)$ contains an edge labeled $x$ into $p \leq q$, then $p \leq q$ is $\sigma x$-enabled.

We can think of $H(\sigma, C)$ as a net in which tokens are passed around as variables are fired. Firing a variable $x$ causes at least one token to be passed from con $(x, C)$ along all edges labeled $x$ to other constraints in which $x$ is exposed, enabling those constraints. The number of tokens that are passed depends on the values of $\sigma(q-p)$ for $p \leq q \in C$, but by Lemma 18(ii), it is always at least one.

Lemma 23 Let $\sigma \tau \in T_{C}$ such that $\sigma \leq_{C} \sigma \tau$. Assume further that $\tau$ contains at least one variable constrained in $C$. Then $H(\sigma \tau, C)$ contains either a cycle all of whose labels are in $\tau$ or an edge out of $*$ whose label is in $\tau$.

Proof. Let $x$ be constrained in $C$ by the constraint $p \leq q$, and suppose that $x$ occurs in $\tau$ at least once. Then $\sigma(p)<\sigma \tau(p)$. Also, $\sigma(q-p) \leq \sigma \tau(q-$ $p)$, since $\sigma \leq_{C} \sigma \tau$. Combining these inequalities, we obtain $\sigma(q)<\sigma \tau(q)$. By Lemma 17, there must be a $y \in X$ and a prefix $\rho y$ of $\tau$ such that $y$ is $\sigma \rho$-exposed in $q$. Then $H(\sigma \rho, C)$ contains an edge labeled $y$ from con $(y, C)$ to $\operatorname{con}(x, C)$. Since $H(\sigma \rho, C)$ is a subgraph of $H(\sigma \tau, C)$, this edge also exists in $H(\sigma \tau, C)$.

Now either $y$ is unconstrained in $C$, in which case con $(y, C)=*$ and we are done, or we can continue in the same fashion with $y$. Following these edges backwards, we must eventually either arrive at $*$ or cycle.

### 6.7 Equivalence of Problem Instances

In our decidability proof, we will show that as a computation $\sigma$ unfolds, the graph $H(\sigma, C)$ develops in certain ways that occasionally allow us to simplify $C$, for instance by discarding a constraint or a variable. In such cases we will construct a new system $D$ that is structurally simpler than $C$ but equivalent in the sense that $D$ has a solution iff $C$ does. The following definition gives the formal notion of equivalence of systems that we have in mind.

Definition 24 Let $C, D$ be systems of constraints. We write $C \leq D$ if for every $\sigma \in T_{C}$ there is a $\tau \in T_{D}$ such that $\sigma \leq_{X} \tau$. We write $C \equiv D$ and say that $C$ and $D$ are equivalent if both $C \leq D$ and $D \leq C$.

It follows immediately from this definition that if $C \equiv D$, then $C$ has a solution if and only if $D$ does.

### 6.8 Proof of Decidability

Let $C$ be a system of Diophantine constraints. The following three lemmas, Lemmas 25,26 , and 27 , identify three situations that will allow a structural simplification of the system $C$. We suggest that the reader skip the proofs of these lemmas on first reading and go directly to Theorem 28 .

Lemma 25 Let $p \leq q \in C$. If $C$ has an unconstrained variable 0 -exposed in $q$, then

$$
C \equiv C-\{p \leq q\}
$$

Proof. Let $C^{\prime}=C-\{p \leq q\}$. The easier direction is $C \leq C^{\prime}$. If $y$ is $(\sigma, C)$-enabled then $y$ is also $\left(\sigma, C^{\prime}\right)$-enabled, since $y$ is either constrained by the same constraint in $C$ and $C^{\prime}$ or unconstrained in $C^{\prime}$. It follows that $T_{C} \subseteq T_{C^{\prime}}$.

For the other direction, suppose $\sigma \in T_{C^{\prime}}$. Let $x$ be a $C$-unconstrained variable 0 -exposed in $q$. Let $n=|\sigma|$ and let

$$
\tau=\underbrace{x x \cdots x}_{n} \sigma=x^{n} \sigma .
$$

Then $\sigma \leq_{X} \tau$. We show that $\tau \in T_{C}$. Certainly $x^{n} \in T_{C}$, since $x$ is unconstrained. It remains to show that $\sigma \in T_{C}^{x^{n}}$. Resetting and using Lemma 11, it suffices to show $\sigma \in T_{\operatorname{inc}_{x^{n}}(C)}$. Thus we need to show that for any prefix $\rho y$ of $\sigma, y$ is $\left(\rho, \operatorname{inc}_{x^{n}}(C)\right)$-enabled. This follows from the fact that $y$ is $\left(\rho, C^{\prime}\right)$-enabled: for any $f \leq g \in C^{\prime}$,

$$
\begin{aligned}
\rho\left(\text { inc }_{x^{n}}(g-f)\right) & =\rho x^{n}(g)-\rho(f) \quad \text { since } x \text { does not occur in } f \\
& \geq \rho(g-f),
\end{aligned}
$$

and for the constraint $p \leq q$,

$$
\begin{aligned}
\rho\left(\mathbf{i n c}_{x^{n}}(q-p)\right) & =\rho x^{n}(q)-\rho(p) & & \text { since } x \text { does not occur in } p \\
& \geq \rho(q)+n-\rho(p) & & \text { by Lemmas } 17 \text { and 18(i) } \\
& \geq \rho(q)+n-|\rho| & & \text { since } p \text { is linear } \\
& >0 & & \text { since }|\rho|<n .
\end{aligned}
$$

Lemmas 26 and 27 deal with two different kinds of cycles that can arise in $H(\sigma, C)$. The first is used when the cycle is a self-loop on a single vertex, and the latter is used when the cycle has at least two vertices.

Lemma 26 If $H(\epsilon, C)$ has a self-loop labeled $x$ on vertex $p \leq q$, and if $x$ is (0,C)-enabled, let

$$
C^{\prime}= \begin{cases}(C-\{p \leq q\}) \cup\{p-x \leq q-x\}, & \text { if } q-x \in \mathbb{N}[X] \\ C-\{p \leq q\}, & \text { otherwise. }\end{cases}
$$

Then $C \equiv C^{\prime}$.
Proof. Since $x$ is 0 -exposed in $q$, by Definition 16 that $q$ has a term of the form $a x^{k}$ where $a, k \in \mathbb{N}$ and $a, k \geq 1$; i.e., $q$ can be written $q^{\prime}+x^{k}$ with $q^{\prime} \in \mathbb{N}[X]$. If the first alternative in the definition of $C^{\prime}$ holds, i.e. if $q$ has a linear term $a x$, then we can take $k=1$. If the second alternative holds, we can take $k>1$. Let us call these two cases (i) and (ii), respectively. Either way, since con $(x, C)$ is $p \leq q, x$ also occurs in $p$, and since $p$ is linear, $p=p^{\prime}+x$ for some $p^{\prime} \in \mathbb{N}[X]$.

First we show $C \leq C^{\prime}$. This is immediate for case (ii) as in Lemma 25. For case (i), note that $q-p=q^{\prime}-p^{\prime}$. Thus for any $\sigma \in X^{*}$, any variable $y \in X-\{x\}$ is $(\sigma, C)$-enabled iff it is $\left(\sigma, C^{\prime}\right)$-enabled, and since $x$ is unconstrained in $C^{\prime}, x$ is always ( $\sigma, C^{\prime}$ )-enabled. It follows that $T_{C} \subseteq T_{C^{\prime}}$, thus $C \leq C^{\prime}$.

Now we show $C^{\prime} \leq C$ for both cases. Let $\sigma \in T_{C^{\prime}}$, and let $n=\max \{2,|\sigma|\}$. Let $\sigma^{\prime}$ be obtained by deleting all occurrences of $x$ from $\sigma$, and let $\tau=x^{n} \sigma^{\prime}$. Then $\sigma \leq_{x} \tau$. We claim that $\tau \in T_{C}$. Since $x$ is $\mathbf{0}$-exposed in $q$ and $(\mathbf{0}, C)$ enabled, by Lemmas 17 and 18(i), $x^{n} \in T_{C}$, so we need only prove that
$\sigma^{\prime} \in T_{C}^{x^{n}}$. Resetting by Lemma 11 , it suffices to prove that $\sigma^{\prime} \in T_{\mathbf{i n c}_{x} n(C)}$. We need to show that for any prefix $\rho^{\prime} y$ of $\sigma^{\prime}, y$ is $\left(\rho^{\prime}\right.$, inc $_{x^{n}}(C)$ )-enabled. This will follow from the fact that $y$ is $\left(\rho, C^{\prime}\right)$-enabled, where $\rho y$ is the unique prefix of $\sigma$ such that $\rho^{\prime} y$ is $\rho y$ with all occurrences of $x$ removed (note $y \neq x$, since it occurs in $\sigma^{\prime}$ ).

Suppose $\rho$ has $m$ occurrences of $x$. For any $f \leq g \in C-\{p \leq q\}$,

$$
\begin{aligned}
\rho^{\prime}\left(\operatorname{inc}_{x^{n}}(g-f)\right) & =\rho^{\prime} x^{n}(g)-\rho(f) \quad \text { since } x \text { does not occur in } f \\
& =\rho x^{n-m}(g)-\rho(f) \\
& \geq \rho(g)-\rho(f) \\
& =\rho(g-f)
\end{aligned}
$$

For the argument involving constraint $p \leq q$, we split on cases. In case (i),

$$
\begin{aligned}
\rho^{\prime}\left(\text { inc }_{x^{n}}(q-p)\right) & =\rho^{\prime} x^{n}\left(q^{\prime}-p^{\prime}\right) \\
& =\rho^{\prime} x^{n}\left(q^{\prime}\right)-\rho\left(p^{\prime}\right) \quad \text { since } x \text { does not occur in } p^{\prime} \\
& =\rho x^{n-m}\left(q^{\prime}\right)-\rho\left(p^{\prime}\right) \\
& \geq \rho\left(q^{\prime}\right)-\rho\left(p^{\prime}\right) \\
& =\rho\left(q^{\prime}-p^{\prime}\right) .
\end{aligned}
$$

In case (ii),

$$
\begin{aligned}
\rho^{\prime}\left(\operatorname{inc}_{x^{n}}(q-p)\right) & =\rho^{\prime} x^{n}(q-p) \\
& =\rho^{\prime} x^{n}\left(q^{\prime}\right)+\rho^{\prime} x^{n}\left(x^{k}\right)-\rho^{\prime} x^{n}\left(p^{\prime}\right)-\rho^{\prime} x^{n}(x) \\
& \geq \delta_{x}^{n}\left(x^{k}\right)-\rho^{\prime}\left(p^{\prime}\right)-\delta_{x}^{n}(x) \\
& \geq n^{k}-(n-1)-n \\
& \geq(n-1)^{2} \\
& >0 .
\end{aligned}
$$

Lemma 27 If there is a cycle in $H(\epsilon, C)$ on vertices

$$
D=\left\{p_{0} \leq q_{0}, \ldots, p_{n-1} \leq q_{n-1}\right\},
$$

then $C \equiv C^{\prime}$, where

$$
\begin{aligned}
p^{\prime} & =\sum_{i=0}^{n-1} p_{i} \\
q^{\prime} & =\sum_{i=0}^{n-1} q_{i} \\
C^{\prime} & =(C-D) \cup\left\{p^{\prime} \leq q^{\prime}\right\}
\end{aligned}
$$

Proof. First we show $C \leq C^{\prime}$. As above, it suffices to show that for any assignment $\sigma \in T_{C}$ and variable $y$, if $y$ is $(\sigma, C)$-enabled then $y$ is $\left(\sigma, C^{\prime}\right)$ enabled. If $\boldsymbol{\operatorname { c o n }}(y, C) \notin D$, then $\boldsymbol{\operatorname { c o n }}\left(y, C^{\prime}\right)=\boldsymbol{\operatorname { c o n }}(y, C)$, thus $y$ is $(\sigma, C)$ enabled iff it is $\left(\sigma, C^{\prime}\right)$-enabled. Otherwise, if $\boldsymbol{\operatorname { c o n }}(y, C) \in D$, say $p_{k} \leq q_{k}$ for some $0 \leq k \leq n-1$, then $\operatorname{con}\left(y, C^{\prime}\right)$ is $p^{\prime} \leq q^{\prime}$. Since $\sigma \in T_{C}$, we have $\sigma\left(p_{i}\right) \leq \sigma\left(q_{i}\right), 0 \leq i \leq n-1$. Moreover, since $y$ is $(\sigma, C)$-enabled, we have $\sigma\left(p_{k}\right)<\sigma\left(q_{k}\right)$. Thus $\sigma\left(p^{\prime}\right)<\sigma\left(q^{\prime}\right)$, so $y$ is $\left(\sigma, C^{\prime}\right)$-enabled.

Now we show $C^{\prime} \leq C$. Assume without loss of generality that the vertices in $D$ occur on the cycle of $H(\epsilon, C)$ in the order $p_{0} \leq q_{0}, \ldots, p_{n-1} \leq q_{n-1}$ and that $y_{i}$ is the label on the edge from $p_{i} \leq q_{i}$ to $p_{i+1} \leq q_{i+1}, 0 \leq i \leq n-1$ (arithmetic on subscripts is modulo $n$ ).

The intuitive idea behind the following argument is that if some $y_{i}$ is enabled, then firing $y_{i}$ enables $y_{i+1}$, and so on; thus we can imagine a token being passed around the cycle $D$, enabling whichever $p_{j} \leq q_{j} \in D$ is needed.

Let $\sigma \in T_{C^{\prime}}$. We construct by induction on the length of $\sigma$ a string $\sigma^{\prime} \in T_{C}$ such that $\sigma \leq_{X, C^{\prime}} \sigma^{\prime}$. Define $\epsilon^{\prime}=\epsilon$. Now suppose $\sigma y \in T_{C^{\prime}}$ and $\sigma^{\prime}$ has been defined. By the induction hypothesis,
(i) $\sigma \leq_{X, C^{\prime}} \sigma^{\prime}$
(ii) $\sigma^{\prime} \in T_{C}$.

Since $y$ is $\left(\sigma, C^{\prime}\right)$-enabled, by (i) we have that $y$ is $\left(\sigma^{\prime}, C^{\prime}\right)$-enabled.
If $\boldsymbol{\operatorname { c o n }}(y, C)$ is in $C-D$ or $\boldsymbol{\operatorname { c o n }}(y, C)=*$, let $(\sigma y)^{\prime}=\sigma^{\prime} y$. Then $\sigma y \leq_{x}$ $(\sigma y)^{\prime}$, and since $\boldsymbol{c o n}(y, C)=\boldsymbol{c o n}\left(y, C^{\prime}\right), y$ is $\left(\sigma^{\prime}, C\right)$-enabled. Moreover, $\sigma y \leq_{C^{\prime}} \sigma^{\prime} y$ by Lemma 14(iii).

If $\boldsymbol{\operatorname { c o n }}(y, C)$ is in $D$, say $p_{k} \leq q_{k}$, then $\boldsymbol{\operatorname { c o n }}\left(y, C^{\prime}\right)$ is $p^{\prime} \leq q^{\prime}$. By (i) and (ii),

$$
\begin{aligned}
\sigma^{\prime}\left(p^{\prime}\right) & <\sigma^{\prime}\left(q^{\prime}\right), \\
\sigma^{\prime}\left(p_{i}\right) & \leq \sigma^{\prime}\left(q_{i}\right), \quad 0 \leq i \leq n-1
\end{aligned}
$$

It follows that there must exist an $i, 0 \leq i \leq n-1$, such that

$$
\begin{equation*}
\sigma^{\prime}\left(p_{i}\right)<\sigma^{\prime}\left(q_{i}\right) \tag{6.10}
\end{equation*}
$$

Define

$$
(\sigma y)^{\prime}=\sigma^{\prime} y_{i} y_{i+1} y_{i+2} \cdots y_{k-1} y
$$

(the sequence $i, i+1, \ldots, k-1$ wraps modulo $n$ if necessary). Then $\sigma y \leq_{x}$ $(\sigma y)^{\prime}$. By $(6.10), y_{i}$ is $\left(\sigma^{\prime}, C\right)$-enabled. Since each $y_{j}$ is 0 -exposed in $q_{j+1}$, $0 \leq j \leq n-1$, it follows inductively that each $y_{j}$ is $\left(\sigma^{\prime} y_{i} y_{i+1} \cdots y_{j-1}, C\right)$ enabled, and $y$ is $\left(\sigma^{\prime} y_{i} y_{i+1} \cdots y_{k-1}, C\right)$-enabled. Thus $\sigma^{\prime} y_{i} y_{i+1} \cdots y_{k-1} y \in T_{C}$.

It remains to show that $\sigma y \leq_{C^{\prime}}(\sigma y)^{\prime}$. For $p \leq q$ in $C-D$,

$$
\begin{aligned}
(\sigma y)^{\prime}(q-p) & =(\sigma y)^{\prime}(q)-(\sigma y)^{\prime}(p) \\
& \geq \sigma y(q)-(\sigma y)^{\prime}(p) \\
& =\sigma y(q)-\sigma y(p) \\
& =\sigma y(q-p) .
\end{aligned}
$$

$$
=\sigma y(q)-\sigma y(p) \quad \text { since the } y_{i} \text { do not appear in } p
$$

For $p^{\prime} \leq q^{\prime}$, since each $y_{j}$ is 0 -exposed in $q_{j+1}$ and hence also in $q^{\prime}$, by Lemma 18(ii) we have

$$
\begin{align*}
(\sigma y)^{\prime}\left(q^{\prime}-p^{\prime}\right) & =\sigma^{\prime} y_{i} y_{i+1} y_{i+2} \cdots y_{k-1} y\left(q^{\prime}-p^{\prime}\right) \\
& \geq \sigma^{\prime} y_{i+1} y_{i+2} \cdots y_{k-1} y\left(q^{\prime}-p^{\prime}\right) \\
& \geq \sigma^{\prime} y_{i+2} \cdots y_{k-1} y\left(q^{\prime}-p^{\prime}\right) \\
& \geq \cdots \\
& \geq \sigma^{\prime} y\left(q^{\prime}-p^{\prime}\right) \tag{6.11}
\end{align*}
$$

By Lemma 14(iii) and the induction hypothesis, (6.11) is bounded below by $\sigma y\left(q^{\prime}-p^{\prime}\right)$.
Theorem 28 It is decidable whether a given instance $C$ of the NRP has a solution.

Proof. We proceed by induction on the complexity of $C$. If $C=\emptyset$, then all variables are unconstrained and therefore enabled, thus we can increment $x_{0}$ immediately. Otherwise assume $C$ is nonempty.

We identify a number of cases below, each of which allows us to reduce the size of $C$ in some respect (either fewer constraints or fewer constrained variables). In each case, the induction hypothesis gives a procedure for deciding whether the smaller system has a solution, and this will determine whether $C$ has a solution.

Case $1 C$ contains an unconstrained ( $\mathbf{0}, C$ )-exposed variable. By Lemma $25, C$ is equivalent to a system with fewer constraints.

Case $2 H(\epsilon, C)$ has a self-loop labeled $x$, and $x$ is $(0, C)$-enabled. By Lemma 26, $C$ is equivalent to a system with either fewer constrained variables or fewer constraints.

Case $3 H(\epsilon, C)$ has a cycle on a set of at least two vertices. By Lemma $27, C$ is equivalent to a system with fewer constraints.

Case 4 None of Cases 1,2 , or 3 apply. In this case, consider the set $T_{C}^{\text {adm }}$ consisting of all admissible strings in $T_{C}$. The set $T_{C}^{\text {adm }}$ contains the empty string $\epsilon$ and is closed under the prefix relation, so it is a tree. For any $\sigma \in T_{C}^{\text {adm }}, \sigma x \in T_{C}^{\text {adm }}$ iff $x$ is $(\sigma, C)$-enabled but not $(\sigma, C)$-inhibited. By Lemma $22, C$ has a solution if and only if it has one in $T_{C}^{\text {adm }}$.

Now let $T_{C}^{\prime}$ be the subtree of $T_{C}^{\text {adm }}$ obtained by deleting all strings containing a proper prefix of the form $\sigma \tau$, where $|\tau|>|X|$ and $\sigma \leq_{C} \sigma \tau$. The tree $T_{C}^{\prime}$ has no infinite paths, since Dickson's Lemma (Lemma 15) says that any infinite path must contain $v_{0}, v_{1}, v_{2}, \ldots$ such that each $v_{i}$ is a proper prefix of $v_{i+1}$ and each $v_{i} \leq_{C} v_{i+1}$; thus $v_{0} \leq_{C} v_{|X|+1}$ and the difference in their lengths is at least $|X|+1$, so this infinite path would be pruned in the construction of $T_{C}^{\prime}$. By König's Lemma, $T_{C}^{\prime}$ is finite, since it is finitely branching. The tree $T_{C}^{\prime}$ can be constructed effectively since the conditions for extending a branch and for pruning are effective.

Since any extension in $T_{C}$ of a solution is a solution, $C$ has a solution iff it has a solution of the form $\sigma \tau \in T_{C}^{\text {adm }}$ for some leaf $\sigma$ of $T_{C}^{\prime}$. The leaves $\sigma$ are of two types, not necessarily mutually exclusive:
(i) All $(\sigma, C)$-enabled variables are $(\sigma, C)$-inhibited. Leaves of this form are leaves of $T_{C}^{\mathrm{adm}}$, since they have no $C$-admissible extensions.
(ii) The leaf $\sigma$ is of the form $\tau \rho$, where $\tau \leq_{C} \tau \rho$ and $|\rho|>|X|$. Leaves of this form are not necessarily leaves of $T_{C}^{\text {adm }}$, but are obtained by pruning $T_{C}^{\text {adm }}$ in the construction of $T_{C}^{\prime}$.

If $\sigma\left(x_{0}\right)>0$ or $x_{0}$ is $(\sigma, C)$-enabled for some leaf $\sigma$, we are done: in the former case, $\sigma$ is a solution, and in the latter, $\sigma x_{0}$ is a solution. Otherwise,
there is no admissible solution extending a leaf of the form (i). Thus we are left with leaves of the form (ii). For each such leaf $\tau \rho$, where $\tau \leq_{C} \tau \rho$ and $|\rho|>|X|$, since $\tau \rho$ is $C$-admissible, for every prefix $v x$ of $\rho$, either

- $x$ is constrained in $C$,
- $x$ is $(\tau v, C)$-exposed, or
- $\tau v(x)=0$.

Suppose $\rho$ contains a variable constrained in $C$. By Lemma 23, $H(\tau \rho, C)$ contains either an edge out of $*$ or a cycle whose labels are in $\rho$. If the former, we revert to Case 1 after resetting. If the latter and the cycle is of length at least two, we revert to Case 3 after resetting. Otherwise there is a self-loop in $H(\tau \rho, C)$ with label $x$, where $v x$ is a prefix of $\rho$. If that self-loop already exists in $H(\tau v, C)$, then since $x$ is $\tau v$-enabled, we revert to Case 2 after resetting. Otherwise, let $v y$ be the shortest prefix of $\rho$ such that $H(\tau v y, C)$ contains that self-loop. By Lemma 18(v), $x$ is $\tau v y$-enabled, and we revert to Case 2 after resetting.

If all variables occurring in $\rho$ are unconstrained in $C$ and at least one is $(\tau v, C)$-exposed for some prefix $v$ of $\rho$, then $H(\tau v, C)$ has an edge out of $*$, and we revert to Case 1 after resetting.

Finally, if all variables occurring in $\rho$ are unconstrained in $C$ and not ( $\tau \rho, C$ )-exposed, we must have $\tau v(x)=0$ for every prefix $v x$ of $\rho$, otherwise the string would not be admissible. But since $|\rho|>|X|$, at least one variable must be fired twice, so this situation cannot occur.
