Discrete optimization

What is a discrete optimization problem?

- Find a solution S in a *finite set* of feasible solutions $\mathcal{F} \subset \{0, 1\}^n$
- Maximize/minimize an objective function f(S)

Some problems are in P:

Min Spanning Tree, Max Flow, Min Cut, Max Matching,...

Many problems are NP-hard:

Traveling Salesman, Max Clique, Max Cut, Set Cover, Knapsack,...

What makes continuous optimization tractable?

< ロ > < 同 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ >

Continuous optimization

What makes continuous optimization tractable?

A function $f : \mathbb{R}^n \to \mathbb{R}$ can be minimized efficiently, if it is convex.

A function $f : \mathbb{R}^n \to \mathbb{R}$ can be maximized efficiently, if it is concave.

Continuous optimization

What makes continuous optimization tractable?

A function $f : \mathbb{R}^n \to \mathbb{R}$ can be minimized efficiently, if it is convex.

A function $f : \mathbb{R}^n \to \mathbb{R}$ can be maximized efficiently, if it is concave.

Discrete analogy? Not so obvious... *f* is now a set function, or equivalently

$$f: \{\mathbf{0},\mathbf{1}\}^n \to \mathbb{R}.$$

What are submodular functions?

- Is submodularity more like convexity or concavity?
- Ontinuous relaxations for submodular optimization problems.
- Hardness from symmetric instances.
- Where do we go next...

From concavity to submodularity

Concavity:

 $f:\mathbb{R} \to \mathbb{R}$ is concave,

if the derivative f'(x) is non-increasing in *x*.

From concavity to submodularity

Concavity:

 $f: \mathbb{R} \to \mathbb{R}$ is concave,

if the derivative f'(x) is non-increasing in *x*.

Submodularity:

 $f: \{0, 1\}^n \to \mathbb{R}$ is submodular,

▲ 同 ▶ | ▲ 三 ▶

if $\forall i$, the discrete derivative $\partial_i f(x) = f(x + e_i) - f(x)$ is non-increasing in *x*.

Equivalent definitions

(1) Define the marginal value of element *j*,

$$f_{S}(j) = f(S \cup \{j\}) - f(S).$$

f is submodular, if
$$\forall S \subset T, j \notin T$$

ъ

 $f_{\mathcal{S}}(j) \geq f_{\mathcal{T}}(j).$

Equivalent definitions

(1) Define the marginal value of element *j*,

$$f_{S}(j) = f(S \cup \{j\}) - f(S).$$

f is submodular, if $\forall S \subset T, j \notin T$:

 $f_{\mathcal{S}}(j) \geq f_{\mathcal{T}}(j).$

(2) A function $f : 2^{[n]} \to \mathbb{R}$ is submodular if for any S, T,

 $f(S \cup T) + f(S \cap T) \leq f(S) + f(T).$

Where do submodular functions appear?

1. Foundations of combinatorial optimization:

[Edmonds, Lovász, Schrijver... 70's-90's]

rank functions of matroids, polymatroids, matroid intersection, submodular flows, submodular minimization \rightarrow submodular functions often appear in the background of P-time solvable problems.

3. Machine learning:

[Guestrin, Krause, Gupta, Golovin, Bilmes,... 2005-now]

submodular functions often appear as objective functions of machine learning tasks such as sensor placement, document summarization or active learning \rightarrow simple algorithms such as Greedy or Local Search work well.

- What are submodular functions?
- Is submodularity more like convexity or concavity?
- Ontinuous relaxations for submodular optimization problems.
- Hardness from symmetric instances.
- Where do we go next...

- Argument for concavity: Definition looks more like concavity *non-increasing* discrete derivatives.
- Argument for convexity: Submodularity seems to be more useful for *minimization* than maximization.

- Argument for concavity: Definition looks more like concavity *non-increasing* discrete derivatives.
- Argument for convexity: Submodularity seems to be more useful for *minimization* than maximization.

Theorem (Grötschel-Lovász-Schrijver, 1981; Iwata-Fleischer-Fujishige / Schrijver, 2000)

There is an algorithm that computes the minimum of any submodular function $f : \{0,1\}^n \to \mathbb{R}$ in poly(n) time (using value queries, f(S) = ?).

Convex aspects of submodular functions

Why is it possible to minimize submodular functions?

- The combinatorial algorithms are sophisticated...
- But there is a simple explanation: the *Lovász extension*.

Convex aspects of submodular functions

Why is it possible to minimize submodular functions?

- The combinatorial algorithms are sophisticated...
- But there is a simple explanation: the Lovász extension.

• Submodular function $f \longrightarrow$ convex function f^L ,

$$f^{L}(\mathbf{x}) = \mathbb{E}_{\lambda \in [0,1]}[f(\{i : \mathbf{x}_{i} > \lambda\})].$$

- f^L can be minimized efficiently.
- A minimizer of $f^{L}(x)$ can be converted into a minimizer of f(S).

Concave aspects?

Recall definition: non-increasing discrete derivatives.

 $f: \{0, 1\}^n \to \mathbb{R}$ is submodular,

if $\forall i$, the discrete derivative $\partial_i f(x) = f(x + e_i) - f(x)$ is non-increasing in *x*.

• Looks like concavity.

Concave aspects?

Recall definition: non-increasing discrete derivatives.

 $f: \{0, 1\}^n \to \mathbb{R}$ is submodular,

if $\forall i$, the discrete derivative $\partial_i f(x) = f(x + e_i) - f(x)$ is non-increasing in *x*.

- Looks like concavity.
- But problems involving maximization of submodular functions are typically NP-hard! (Max Cut, Max Coverage,)

So what's going on?

The Greedy Algorithm

Problems in the form: max{ $f(S) : S \in I$ } where *f* is monotone (non-decreasing) submodular. $(S \subset T \Rightarrow f(S) \le f(T))$

The Greedy Algorithm: [Nemhauser, Wolsey, Fisher '78] Pick elements one-by-one, maximizing the gain in f(S), while maintaining $S \in \mathcal{I}$.

< □ > < □ > < □ > < □ >

The Greedy Algorithm

Problems in the form: $\max\{f(S) : S \in \mathcal{I}\}\$ where *f* is monotone (non-decreasing) submodular. $(S \subset T \Rightarrow f(S) \leq f(T))$

The Greedy Algorithm: [Nemhauser, Wolsey, Fisher '78]

Pick elements one-by-one, maximizing the gain in f(S), while maintaining $S \in \mathcal{I}$.

S i, maximizing
$$f(S+i) - f(S)$$

Theorem (Nemhauser, Wolsey, Fisher '78)

If *f* is monotone submodular, Greedy finds a solution of value at least $(1 - 1/e) \times$ optimum for the problem max{ $f(S) : |S| \le k$ }.

Optimality: [NW'78] No algorithm using a polynomial number of queries to f can achieve a factor better than $1 - \frac{1}{e^{2}} + \frac{1}{e^{2}}$

Jan Vondrák (IBM Almaden)

Applications of the Greedy Algorithm

Greedy Algorithm provides: (using [NWF '78])

(1 − 1/e)-approximation for various problems in optimization and machine learning in the form max{f(S) : |S| ≤ k};

marketing on social networks [Kempe-Kleinberg-Tardos '03], optimal sensor placement [Krause-Guestrin-et al. '06-'10]

 2 1/2-approximation for problems in the form max{f(S) : S ∈ I} where I is a matroid;

e.g. welfare maximization in combinatorial auctions with submodular bidders [Lehmann-Lehmann-Nisan '01]

< ロ > < 同 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ >

Applications of the Greedy Algorithm

Greedy Algorithm provides: (using [NWF '78])

(1 − 1/e)-approximation for various problems in optimization and machine learning in the form max{f(S) : |S| ≤ k};

marketing on social networks [Kempe-Kleinberg-Tardos '03], optimal sensor placement [Krause-Guestrin-et al. '06-'10]

 2 1/2-approximation for problems in the form max{f(S) : S ∈ I} where I is a matroid;

Questions that don't seem to be answered by the greedy algorithm:

- Optimal approximation for max{*f*(*S*) : *S* ∈ *I*} where *f* is monotone submodular and *I* forms a matroid
- Optimization of non-monotone submodular functions
- More general constraints, or combinations of simple ones

- What are submodular functions?
- Is submodularity more like convexity or concavity?
- Ontinuous relaxations for submodular optimization problems.
- Hardness from symmetric instances.
- Where do we go next...

Continuous relaxation for submodular maximization?

The Lovász extension is convex — not suitable for maximization.

2 There is also a "concave closure". However, NP-hard to evaluate!

Multilinear extension of *f*:

- *F*(*x*) = 𝔼[*f*(*x̂*)], where *x̂* is obtained by rounding each *x_i* randomly to 0/1 with probabilities *x_i*.
- F(x) is neither convex nor concave; it is multilinear and $\frac{\partial^2 F}{\partial x^2} = 0$.
- $F(x + \lambda \vec{d})$ is a *concave* function of λ , if $\vec{d} \ge 0$.

The Continuous Greedy Algorithm [V. '08]

Problem: max{ $F(x) : x \in P$ }, *F* multilinear extension of a *monotone submodular function*.

For each $x \in P$, define v(x) by $v(x) = argmax_{v \in P}(v \cdot \nabla F|_x).$ Define a curve x(t): x(0) = 0 $\frac{dx}{dt} = v(x)$

Run this process for $t \in [0, 1]$ and return x(1).

Claim: $x(1) \in P$ and $F(x(1)) \ge (1 - 1/e)OPT$.

Analysis of Continuous Greedy

Evolution of the fractional solution:

- Differential equation: $x(0) = 0, \frac{dx}{dt} = v(x).$
- Chain rule:

Solve the differential equation:

$$F(x(t)) \geq (1 - e^{-t}) \cdot OPT.$$

Applications of the multilinear relaxation

Algorithms:

- (1 1/e)-approximation for the problem max $\{f(S) : S \in \mathcal{I}\}$ where f is monotone submodular and \mathcal{I} is a matroid [Calinescu-Chekuri-Pál-V. '08]
- 2 $(1 1/e \epsilon)$ -approximation for maximizing subject to O(1) linear constraints: max{ $f(S) : \forall i; \sum_{j \in S} c_{ij} \leq 1$ } [Kulik-Shachnai-Tamir '09]
- 1/e-approximation for the same problems with non-monotone submodular valuations [Feldman-Naor-Schwartz '11]
- Approximations for more general constraints [Chekuri-Zenklusen-V. '11]

Applications of the multilinear relaxation

Algorithms:

- (1 1/e)-approximation for the problem max $\{f(S) : S \in \mathcal{I}\}$ where f is monotone submodular and \mathcal{I} is a matroid [Calinescu-Chekuri-Pál-V. '08]
- 2 $(1 1/e \epsilon)$ -approximation for maximizing subject to O(1) linear constraints: max{ $f(S) : \forall i; \sum_{j \in S} c_{ij} \leq 1$ } [Kulik-Shachnai-Tamir '09]
- 1/e-approximation for the same problems with non-monotone submodular valuations [Feldman-Naor-Schwartz '11]
- Approximations for more general constraints [Chekuri-Zenklusen-V. '11]

Open question: What is the best approximation for the problem $max{F(x) : x \in P}$ when *F* is non-monotone submodular?

(We know a $1/e \simeq 0.36$ -approximation, and better than 0.48 is impossible.)

A (10) A (10)

- What are submodular functions?
- Is submodularity more like convexity or concavity?
- Ontinuous relaxations for submodular optimization problems.
- Hardness from symmetric instances.
- Where do we go next...

Hardness from multilinear relaxation

Symmetry gap: ratio $\gamma = \overline{OPT} / OPT$ between the best *symmetric* and the best *asymmetric* solution for the multilinear relaxation

 $\frac{OPT}{OPT} = \max\{F(x) : x \in P\}$ $\frac{OPT}{OPT} = \max\{F(x) : x \in P_{sym}\}$

Hardness from multilinear relaxation

Symmetry gap: ratio $\gamma = \overline{OPT} / OPT$ between the best *symmetric* and the best *asymmetric* solution for the multilinear relaxation

 $\frac{OPT}{OPT} = \max\{F(x) : x \in P\}$ $\frac{OPT}{OPT} = \max\{F(x) : x \in P_{sym}\}$

Idea: Based on such an example, we can generate similar instances such that an efficient algorithm will find only "symmetric solutions", hence it cannot get close to the optimum.

Theorem (informal)

For an instance of submodular optimization with symmetry gap γ and any $\epsilon > 0$, there is a family of "similar" instances \mathcal{F} such that no efficient algorithm can achieve a $(\gamma + \epsilon)$ -approximation on \mathcal{F} .

(using value queries [V. '09], or on explicit instances assuming that NP \neq RP [Dobzinski, V. '12])

Consequences: unification of known hardness results, some new results.

- 1 1/e is optimal for max $\{f(S) : |S| \le k\}$, f monotone [Nemhauser, Wolsey '78]
- 1/2 is optimal for max{f(S) : S ⊆ N}, f non-monotone submodular [Feige,Mirrokni,V. '06][Buchbinder,Feldman,Naor,Schwartz '12]
- 0.49 cannot be achieved for max{f(S) : |S| ≤ k}, f non-monotone submodular [Oveis Gharan, V. '11]
- no constant factor can be achieved for max{f(S) : S ∈ B},
 f non-monotone submodular and B bases in a matroid [V. '09]

Connections with integrality gap and UG-hardness

- Symmetry gap implies hardness for a submodular optimization problem: in the oracle model [V. 109] and also NP-hardness for explicit instances [Dobzinski,V. 12].
- It is equal to the integrality gap of a related LP formulation.
- For *Min-CSP problems with the Not-Equal predicate*, this also implies hardness assuming the *Unique-Games Conjecture*.

[Manokaran,Naor,Raghavendra,Schwartz '08] [Ene,V.,Wu '13]

Example: a Hypergraph Labeling Problem

Hypergraph Labeling: (problem in Min-CSP form) Given a hypergraph H = (V, E) with color lists $L(v) \subseteq [k] \forall v \in V$, find a coloring $\ell(v) \in L(v)$ that minimizes the number of hyperedges with more than 1 color.

Example: a Hypergraph Labeling Problem

Hypergraph Labeling: (problem in Min-CSP form) Given a hypergraph H = (V, E) with color lists $L(v) \subseteq [k] \forall v \in V$, find a coloring $\ell(v) \in L(v)$ that minimizes the number of hyperedges with more than 1 color.

Submodular generalization: Minimize $\sum_{i=1}^{k} f(\ell^{-1}(i))$

- Lovász extension gives a natural convex relaxation
- \longrightarrow k-approximation for Hypergraph Labeling [Chekuri-Ene '11]
- is this best possible? enough to find a symmetry/integrality gap

Sperner-style setup: hyperedges are *k*-vertex simplices, scaled copies of a large simplex; vertices on the boundary are allowed to use only the colors of the respective face.

Question: [Ene-V. '14]

What is the minimum possible number of non-monochromatic hyperedges?

Optimal Coloring => Integrality gap

Plausible conjecture: the following "simple coloring" has the minimum number of non-monochromatic hyperedges:

Optimal Coloring => Integrality gap

Plausible conjecture: the following "simple coloring" has the minimum number of non-monochromatic hyperedges:

• LP cost
$$\simeq \frac{1}{n} \cdot \frac{1}{(k-1)!} n^k = \frac{1}{(k-1)!} n^{k-1}$$

- Optimum cost $\simeq \frac{1}{(k-2)!} n^{k-1} = (k-1) \times LP \ cost$
- this would imply that there is no approximation better than (k 1), assuming the Unique Games Conjecture (using [Ene-V-Wu 13])

Proof of the optimality of the "simple coloring"

[Mirzakhani '14]

• Set of vertices = $V_{n,k}$, hyperedges can be identified with $V_{n-1,k}$

• Map monochromatic hyperedges to $V_{n-2,k}$ as in the picture.

Proof of the optimality of the "simple coloring"

[Mirzakhani '14]

- Set of vertices = $V_{n,k}$, hyperedges can be identified with $V_{n-1,k}$
- Map monochromatic hyperedges to $V_{n-2,k}$ as in the picture.
- Since two monochromatic hyperedges cannot be neighbors, the mapping is injective.

• #non-mono $\chi \ge |V_{n-1,k}| - |V_{n-2,k}| = \binom{n+k-2}{k-1} - \binom{n+k-3}{k-1} = \binom{n+k-3}{k-2}.$

We have:

Discrete optimization of linear functions \leftrightarrow Linear Programming Minimization of submodular functions \leftrightarrow Lovász Relaxation Maximization of submodular functions \leftrightarrow Multilinear Relaxation

We have:

Discrete optimization of linear functions \leftrightarrow Linear Programming Minimization of submodular functions \leftrightarrow Lovász Relaxation Maximization of submodular functions \leftrightarrow Multilinear Relaxation

Fundamental questions:

- Can we solve every maximization problem with a monotone submodular objective that we can solve with a linear objective (up to constant factors)?
- The best approximations are achieved by randomized algorithms is randomization necessary?

Fundamental questions:

- Can we solve every maximization problem with a monotone submodular objective that we can solve with a linear objective (up to constant factors)?
- The best approximations are achieved by randomized algorithms is randomization necessary?

Practical question: some progress in [Ashwinkumar-V. '14]

Can these algorithms be used in practice — better running times?
