Abstract. Term algebras have wide applicability in computer science. Unfortunately, the decision problem for term algebras has a nonelementary lower bound, which makes the theory and any extension of it intractable in practice. However, it is often more appropriate to consider the bounded class, in which formulae can have arbitrarily long sequences of quantifiers but the quantifier alternation depth is bounded. In this paper we present new quantifier elimination procedures for the first-order theory of term algebras and for its extension with integer arithmetic. The elimination procedures deal with a block of quantifiers of the same type in one step. We show that for the bounded class of at most k quantifier alternations, regardless of the total number of quantifiers, the complexity of our procedures is k-fold exponential (resp. $2k$ fold exponential) for the theory of term algebras (resp. for the extended theory with integers).

1 Introduction

The theory of term algebras, also known as the theory of finite trees, axiomatizes the Herbrand universe. It has wide applicability in computer science. In programming languages many so-called recursive data structures can be modeled as term algebras [19]; in theorem proving it is essential to the unification and disunification problem [18, 3]; in logic programming, it is used to define formal semantics [14]. Other applications can be found in computational linguistics, constraint databases, pattern matching and type theory.

In this paper we consider an arithmetic extension of the theory of term algebras. Our extended language has two sorts; the integer sort $\mathbb{Z}$ and the term sort TA. Intuitively, the language is the set-theoretic union of the language of term algebras and the language of Presburger arithmetic plus the additional length function $(.)^{\mathsf{L}} : \mathsf{TA} \to \mathbb{Z}$. Formulae are formed from term literals and integer literals using logical connectives and quantifications. Term literals are exactly those literals in the language of term algebras. Integer literals are those that

can be built up from integer variables (including the length function applied to TA-terms), the usual arithmetic relations and functions. This type of arithmetic extension has been used in [10, 11] to show that the quantifier-free theory of term algebras with Knuth-Bendix order is NP-complete.

Our interest originates from program verification as term algebras can model a wide range of tree-like data structures. Examples include lists, stacks, counters, trees, records and queues. To verify programs containing these data structures we must be able to reason about these data structures. However, in program verification decision procedures for a single theory are usually not applicable as programming languages often involve multiple data domains, resulting in verification conditions that span multiple theories. A common example of such "mixed" constraints are combinations of data structures with integer constraints on the size of those structures. In [24] we gave a quantifier-elimination procedure for this extended theory.

Unfortunately the theory of term algebras has nonelementary time complexity [7, 3, 22], which makes the theory and any extension of it intractable in practice. However, as observed by many [20, 8], in consideration of the complexity of logic theories, the meaning of a formula soon becomes incomprehensible as the number of quantifier alternations increases. In practice we rarely deal with formulae with a large quantifier alternation depth. Therefore it is worthwhile to investigate the class of formulae which can have arbitrarily long sequences of quantifiers of the same kind while the total number of quantifier alternations is bounded by a constant number. We call such formulae alternation bounded.

In this paper we present new quantifier elimination procedures for the theory of term algebras as well as the extended theory with integers. Our procedures can eliminate a block of quantifiers of the same kind in one step. For the bounded class of at most k quantifier alternations, regardless of the total number of quantifiers, the complexity is k-fold exponential (resp. $2k$ fold exponential) for the theory of term algebras (resp. for the extended theory with integers).

Related Work and Comparison. Presburger arithmetic (PA) was first shown to be decidable in 1929 by the quantifier elimination method [6]. Efficient algorithms were later discovered by Cooper et al [5, 20]. It was shown in [20] and [8], respectively, that the upper bound and the lower bound of the bounded class in the theory of PA is one exponential lower than the whole theory.

The decidability of the first-order theory of term algebras was first shown by Mal'cev using quantifier elimination [17]. This result was reproved in different settings [16, 3, 9, 2, 1, 21, 13, 12, 24]. The lower bound of any theory of pairing functions was shown to be nonelementary in [7]; this result was strengthened in [4] to a hereditarily nonelementary lower bound. This lower bound complexity applies to the theory of term algebras as term algebras with a binary constructor can express pairing functions. Using techniques in [4], [22] showed that theories of finite trees, infinite and rational trees are all hereditarily nonelementary.

Quantifier elimination has been used to obtain decidability results for various extensions of term algebras. [16] showed the decidability of the theory of infinite and rational trees. [2] presented an elimination procedure for term

algebras with membership predicate in the regular tree language. [1] presented an elimination procedure for structures of feature trees with arity constraints. [21] showed the decidability of term algebras with queues. [13] showed the decidability of term powers, which generalize products and term algebras. [24] extended the quantifier elimination procedure in [9] for term algebras with length function.

Traditionally, methods for quantifier elimination for term algebras follow one of two approaches: they either perform transformations in the constructor language [17, 3, 16, 12], or they work in the selector language [9, 21]. In the first approach formulae are reduced to a boolean combination of a specific kind of formulae called "solved forms", which include ordinary literals. In this respect [3] is essentially a dual of [16] with the special formulae being universally quantified. In [12] selectors are used to convert solved forms to quantifier-free formulae. In the second approach, formulae are transformed into a form in which the quantified variable is not embedded in selectors and only occurs in disequalities. Methods following the first approach can deal with a block of quantifiers of the same type in one step. They all rely on the "independence lemma" ([17], page 277, also see Thm. 1 in this paper) which states that "there are enough elements to satisfy a certain set of disequalities and equalities." However, this does not hold in the language with finite signature and length function. Methods following the second approach can only handle a single quantifier at a time.

Our elimination procedures are carried out in the language with both selectors and constructors. The method combines the extraction of integer constraints from term constraints with a reduction of quantifiers on term variables to quantifiers on integer variables.

Paper Organization. Section 2 provides the preliminaries: it introduces the notation and terminology. Section 3 defines term algebras. Section 4 describes a new elimination procedure for the theory of term algebras. Section 5 introduces the theory of term algebras with integer arithmetic and presents the technical machinery for handling the length function. Section 6 presents the main contribution of this paper: it expands the elimination procedure in Section 4 for the extended theory with integers. Section 7 concludes with some ideas for future work. Due to space limitation all proofs have been omitted from this paper. They are available for reference in the extended version of this paper at the first author's website.

2 Preliminaries

We assume the first-order syntactic notions of variables, parameters and quantifiers, and semantic notions of structures, satisfiability and validity as in [6]. We explain concepts and terminology important to this paper as follows.

A signature Σ is a set of parameters (function symbols and predicate symbols) each of which is associated with an arity. The function symbols with arity 0 are

also called constants. The set of Σ-terms $\mathcal{T}(\Sigma, \mathcal{X})$ is recursively defined by: (i) every constant $c \in \Sigma$ or variable $x \in \mathcal{X}$ is a term, and (ii) if $f \in \Sigma$ is an n-place function symbol and $t_1, \ldots, t_n$ are terms, then $f(t_1, \ldots, t_n)$ is a term. If θ is a formula, we use $\Sigma(\theta)$ to denote the set of terms occurring in θ. The length of a term t, written $\mathsf{len}(t)$, is defined recursively by: (i) for any constant a, $\mathsf{len}(a) = 1$, and (ii) for a term $\alpha(t_1, \ldots, t_k)$, $\mathsf{len}(\alpha(t_1, \ldots, t_k)) = \sum_{i=1}^{k} \mathsf{len}(t_i) + 1$.

An atomic formula (atom) is a formula of the form $P(t_1, \ldots, t_n)$ where P is an n-place predicate symbol and $t_1, \ldots, t_n$ are terms (equality is treated as a binary predicate symbol). A literal is an atomic formula or its negation. A variable occurs free in a formula if it is not in the scope of a quantifier. A formula without quantifiers is called quantifier-free. A ground formula is a formula with no variables. A sentence is a formula in which no variable occurs free. Every quantifier-free formula can be put into disjunctive normal form, that is, a disjunction of conjunctions of literals.

We use $\boldsymbol{x}$ to denote a set of variables, say, $x_1, \ldots, x_n$, and $\exists \boldsymbol{x}$ (resp. $\forall x$) as an abbreviation of $\exists x_1, \ldots, \exists x_n$ (resp. $\forall x_1, \ldots, \forall x_n$). When we write $\theta(\boldsymbol{x})$, we mean that $\boldsymbol{x}$ occur free in θ. Any formula θ can be put into prenex form $Q_1 x_1, \ldots, Q_n x_n\, \theta(\boldsymbol{x})$, where Q_i's are either $\exists$ or $\forall$ and $\theta(\boldsymbol{x})$ is quantifier-free. We call $\theta(\boldsymbol{x})$ the matrix of θ. We say that θ has quantifier (alternation) depth m if $Q_1, \ldots, Q_n$ can be divided into m blocks such that all quantifiers in a block are of the same type and quantifiers in two consecutive blocks are different.

A Σ-structure (or Σ-interpretation) $\mathfrak{A}$ is a tuple $\langle A, I \rangle$ where A is a non-empty domain and I is a function that associates each n-place function symbol f (resp. predicate symbol P) with an n-place function $f^{\mathfrak{A}}$ (resp. relation $P^{\mathfrak{A}}$) on A. We usually denote $\mathfrak{A}$ by $\langle A; \Sigma \rangle$ which is called the signature of $\mathfrak{A}$.

A variable assignment σ (or variable valuation) is a function that assigns each variable an element of A. We use $[\![\boldsymbol{x}]\!]\sigma$ to denote the assigned values of $\boldsymbol{x}$ under σ. We write $[\![\boldsymbol{x}]\!]$ when σ is clear from the context. The truth value of a formula is determined by an interpretation and a variable assignment.

A formula θ is satisfiable (or consistent) if it is true under some variable assignment; it is unsatisfiable (or inconsistent) otherwise. A formula θ is valid if it is true under every variable assignment. A formula θ is valid if and only if $\neg\theta$ is unsatisfiable.

By a theory of structure $\mathfrak{A}$, written $\mathsf{Th}(\mathfrak{A})$, we shall mean the class of all valid sentences in $\mathfrak{A}$. We use $\mathsf{BC}_k(\mathfrak{A})$ denote the subclass of $\mathsf{Th}(\mathfrak{A})$ in which all sentences have at most k quantifier alternations.

A theory T is said to admit quantifier elimination if any formula can be equivalently (modulo T) and effectively transformed into a quantifier-free formula. If a theory admits quantifier elimination, then every sentence is reducible to a ground formula. Therefore, if ground literals are decidable, then a quantifier elimination procedure becomes a decision procedure.

Presburger arithmetic (PA) is the first-order theory of addition in the arithmetic of integers. The corresponding language and structure are denoted, respectively, by $\mathscr{L}_{\mathbb{Z}}$ and $\mathfrak{A}_{\mathbb{Z}} = \langle \mathbb{Z}; 0, +, < \rangle$.

We define $\exp_0(f(n)) = f(n)$ and $\exp_{m+1}(f(n)) = 2^{\exp_m(f(n))}$.

3 Term Algebras

We present a general language and structure of term algebras. For simplicity, we do not distinguish syntactic terms in the language from semantic terms in the corresponding structure. The meaning should be clear from the context.

Definition 1. *A term algebra* $\mathfrak{A}_{\mathsf{TA}} : \langle \mathsf{TA}; \mathcal{A}, \mathcal{C}, \mathcal{S}, \mathcal{T} \rangle$ *consists of*

1. TA*: The term domain, which consists of all terms built up from constants by applying constructors. Elements in* TA *are called* TA*-terms.*
2. $\mathcal{A}$*: A finite set of constants: a, b, c, . . .*
3. $\mathcal{C}$*: A finite set of constructors:* $\alpha, \beta, \gamma, \ldots$ *The arity of* α *is denoted by* $\mathsf{ar}(\alpha)$*. An object is* α*-typed (or an* α*-term) if its outmost constructor is* α*.*
4. $\mathcal{S}$*: A finite set of selectors. For a constructor* α *with arity k, there are k selectors* $\mathsf{s}^\alpha_1, \ldots, \mathsf{s}^\alpha_k$ *in* $\mathcal{S}$*. For a term x,* $\mathsf{s}^\alpha_i(x)$ *returns the* i^{th} *component of x if x is an* α*-term and x itself otherwise.*
5. $\mathcal{T}$*: A finite set of testers. For each constructor* α *there is a corresponding tester* Is_α*. For a term x,* $\mathsf{Is}_\alpha(x)$ *is true if and only if x is an* α*-term. In addition there is a special tester* Is_C *such that* $\mathsf{Is}_\mathsf{C}(x)$ *is true if and only if x is a constant. Note that there is no need for individual constant testers as* $x = a$ *serves as* $\mathsf{Is}_a(x)$*.*

We denote by $\mathscr{L}_{\mathsf{TA}}$ *the language for* $\mathfrak{A}_{\mathsf{TA}}$*.*

Unless mentioned otherwise, in this paper we assume that $\mathscr{L}_{\mathsf{TA}}$ is finite. However, the techniques presented here can be modified to handle the case of infinite languages. In particular, the decision problems become considerably easier if we allow $\mathscr{L}_{\mathsf{TA}}$ to have infinitely many constants. We leave the detailed discussion to the extended version of this paper.

The theory of term algebras is axiomatizable as follows [9].

Proposition 1 (Axiomatization of Term Algebras [9]). *Let* z_α *be* $z_1, \ldots, z_{\mathsf{ar}(\alpha)}$*. The following formula schemes, in which variables are implicitly universally quantified over* TA*, axiomatize* $\mathsf{Th}(\mathfrak{A}_{\mathsf{TA}})$*.*

A. $t(x) \neq x$*, if t is built solely by constructors and t properly contains x.*
B. $a \neq b$*,* $a \neq \alpha(x_1 \ldots, x_{\mathsf{ar}(\alpha)})$*, and* $\alpha(x_1 \ldots, x_{\mathsf{ar}(\alpha)}) \neq \beta(y_1, \ldots, y_{\mathsf{ar}(\beta)})$*, if a and b are distinct constants and if* α *and* β *are distinct constructors.*
C. $\alpha(x_1, \ldots, x_{\mathsf{ar}(\alpha)}) = \alpha(y_1, \ldots, y_{\mathsf{ar}(\alpha)}) \rightarrow \bigwedge_{1 \leq i \leq \mathsf{ar}(\alpha)} x_i = y_i$*.*
D. $\mathsf{Is}_\alpha(x) \leftrightarrow \exists\, z_\alpha \alpha(z_\alpha) = x$*;* $\mathsf{Is}_\mathsf{C}(x) \leftrightarrow \bigwedge_{\alpha \in \mathcal{C}} \neg \mathsf{Is}_\alpha(x)$*.*
E. $\mathsf{s}^\alpha_i(x) = y \leftrightarrow (\exists z_\alpha(\alpha(z_\alpha) = x \wedge y = z_i)) \vee (\forall z_\alpha(\alpha(z_\alpha) \neq x) \wedge x = y)$*.*

In general selectors and testers can be defined by constructors and vice versa. One direction has been shown by (D) and (E), which are pure definitional axioms.

Example 1. Consider the LISP list structure

$$\mathfrak{A}_{\mathsf{list}} = \langle \mathsf{list};\ \{\mathsf{nil}\},\ \{\mathsf{cons}\},\ \{\mathsf{car}, \mathsf{cdr}\},\ \{\mathsf{Is}_{\mathsf{cons}}\} \rangle$$

where list denotes the domain, nil denotes the empty list, cons is the 2-place constructor (pairing function) and car and cdr are the corresponding left and right selectors (projectors) respectively. It is not difficult to verify that $\mathfrak{A}_{\mathsf{list}}$ is an instance of term algebras.

We use the notation $\alpha = (\mathsf{s}_1^\alpha, \ldots, \mathsf{s}_k^\alpha)$ to mean that α is a constructor with $\mathsf{ar}(\alpha) = k$ and $\mathsf{s}_1^\alpha, \ldots, \mathsf{s}_k^\alpha$ are the corresponding selectors of α. We call a term t a constructor term (resp. selector term) if the outmost function symbol of t is a constructor (resp. a selector). We assume that no constructor term appears inside selectors as simplification can always be done. For example, $\mathsf{s}_i^\alpha(\alpha(x_1, \ldots, x_k))$ simplifies to x_i $(1 \leq i \leq k)$ and $\mathsf{s}_j^\beta(\alpha(x_1, \ldots, x_k))$ simplifies to $\alpha(x_1, \ldots, x_k)$ for $\alpha \not\equiv \beta$. We use $L, M, N, \ldots$ to denote selector sequences. If $L = \mathsf{s}_1, \ldots, \mathsf{s}_n$, Lx is an abbreviation for $\mathsf{s}_1(\ldots(\mathsf{s}_n(x)\ldots))$. We say a selector term $\mathsf{s}_i^\alpha(t)$ is proper if $\mathsf{Is}_\alpha(t)$ holds. We can make selector terms proper with type information.

Definition 2 (Type Completion). *θ' is a type completion of θ if θ' is obtained from θ by adding tester predicates such that for any term $\mathsf{s}(t)$ exactly one literal of the form $\mathsf{Is}_\alpha(t)$ $(\alpha \in C)$ or $\mathsf{Is}_\mathsf{C}(t)$ is present in θ'.*

Example 2. Let $\alpha = (\mathsf{s}_1^\alpha, \mathsf{s}_2^\alpha)$. A possible type completion for $y = \mathsf{s}_1^\alpha \mathsf{s}_2^\alpha x$ is $y = \mathsf{s}_1^\alpha \mathsf{s}_2^\alpha x \wedge \mathsf{Is}_\alpha(x) \wedge \mathsf{Is}_\mathsf{C}(\mathsf{s}_2^\alpha x)$. With this type information we can simplify $y = \mathsf{s}_1^\alpha \mathsf{s}_2^\alpha x$ to $y = \mathsf{s}_2^\alpha x$ by Axioms (D) and (E) in Prop. 1.

4 A New Quantifier Elimination Procedure for $\mathbf{Th}(\mathfrak{A}_{\mathsf{TA}})$

In this section we present a new quantifier elimination algorithm for the theory of term algebras and show that the algorithm only needs exponential time to eliminate a block of quantifiers of the same kind. The algorithm works mainly in the constructor language while using selectors as auxiliary tools. The algorithm is also the basis for the elimination procedure for the extended theory presented in Section 6.

Normal Form. It is well-known that eliminating arbitrary quantifiers reduces to eliminating existential quantifiers from formulae in the form

$$\exists \boldsymbol{x}(A_1(\boldsymbol{x}) \wedge \ldots \wedge A_n(\boldsymbol{x})), \tag{1}$$

where $A_i(\boldsymbol{x})$ $(1 \leq i \leq n)$ are literals [9]. We can also assume that $A_i's$ are not of the form $x = t$ as $\exists x(x = t \wedge \theta(x, \boldsymbol{y}))$ simplifies to $\theta(t, \boldsymbol{y})$, if x does not occur in t, to $\exists x \theta(x, \boldsymbol{y})$ if $t \equiv x$, and to false by Axiom (A) if t is a term which is built solely by constructors and properly contains x.

Nondeterminism. In this paper all transformations are done on formulae of the form (1). Whenever we say "guess θ", we mean to add a valid disjunction $\bigvee_i \theta_i$ (where θ is one of the disjuncts) to the matrix of (1). When we replace θ by $\bigvee_i \theta_i$ or directly introduce $\bigvee_i \theta_i$, it should be understood that an implicit disjunctive splitting is carried out and we work on each resultant disjunct in the form (1) "simultaneously".

Simplification. For simplicity, in the description of algorithms, we omit tester literals unless they are needed for correctness proof. We may also assume that the matrix of (1) is type complete and basic simplifications are carried out whenever applicable. For example, for a nonempty selector sequence L, we replace $Lx \neq x$ by true and $Lx = x$ by false. Similarly for $t(x) \neq x$ and $t(x) = x$ where $t(x)$ is a term properly containing x.

Notation. In the algorithm we use the following notation: $\boldsymbol{x}$ denote the set of existentially quantified variables; $\boldsymbol{y}$ denote the set of (implicitly) universally quantified parameters; s, t, u denote TA-terms; G, H denote (possibly empty) selector blocks; f, g, h denote index functions with ranges clear from the context; numerical superscripts are parenthesized. Index functions are used to differentiate multiple occurrences of the same variables.

Note that in each step the algorithm manipulates the formula $\exists \boldsymbol{x} : \theta(\boldsymbol{x}, \boldsymbol{y})$ to produce a version of the same form (or multiple versions of the same form in case disjunctions are introduced), and thus in each step $\exists \boldsymbol{x} : \theta(\boldsymbol{x}, \boldsymbol{y})$ refers to the updated version rather than to the original input formula.

Definition 3 (Solved Form). *We say $\theta_{\mathsf{TA}}(\boldsymbol{x}, \boldsymbol{y})$ is in the* solved form *(with respect to $\boldsymbol{x}$), if $\boldsymbol{x}$ are not in equalities, not asserted to be constants and not inside selector terms. We say $\exists \boldsymbol{x}\, \theta_{\mathsf{TA}}(\boldsymbol{x}, \boldsymbol{y})$ is in the solved form if $\theta_{\mathsf{TA}}(\boldsymbol{x}, \boldsymbol{y})$ is.*

The elimination goes as follows. A sequence of equivalence-preserving transformations will bring the input formula into a disjunction of formulae in the solved form which have solutions under any instantiation of parameters. Therefore, the whole block of existential quantifiers $\exists \boldsymbol{x}$ can be eliminated by removing all literals containing $\boldsymbol{x}$ in the matrix.

Algorithm 1. *Input:* $\exists \boldsymbol{x} : \theta(\boldsymbol{x}, \boldsymbol{y})$.

1. *Type Completion. Guess a type completion of $\theta(\boldsymbol{x}, \boldsymbol{y})$ and simplify every selector term to a proper one.*
2. *Elimination of Selector Terms Containing $\boldsymbol{x}$. Replace all selector terms containing x by the corresponding equivalent constructor terms according to Axiom* (E)*. For example $s_1^{\alpha} x = y$ becomes $\exists z_2, \ldots, z_k \alpha(y, z_2, \ldots, z_k) = x$ for $\mathsf{ar}(\alpha) = k$. It may increase the number of existential quantifiers, but leaves parameters unchanged. From now on, $\boldsymbol{x}$ never appear inside selector terms.*
3. *Elimination of Equalities between Constructor Terms. Replace*
$$\alpha(t_1, \ldots, t_i) = \alpha(t'_1, \ldots, t'_i) \tag{2}$$
by $\bigwedge_{1 \leq i \leq k} t_i = t'_i$. Repeat until no equality of the form (2) *appears.*
4. *Elimination of Disequalities between Constructor Terms. Replace*
$$\alpha(t_1, \ldots, t_i) \neq \alpha(t'_1, \ldots, t'_i) \tag{3}$$
by $\bigvee_{1 \leq i \leq k} t_i \neq t'_i$. Repeat until no equality of the form (3) *appears. At this point we may assume that each disjunct (that has not been simplified to* false*) is in the form*
$$\exists \boldsymbol{x} : \Big[\bigwedge_i x_{f(i)} \neq t_i(\boldsymbol{x}, \boldsymbol{y}) \wedge \bigwedge_i G_i y_{g(i)} \neq s_i(\boldsymbol{x}, \boldsymbol{y}) \wedge \bigwedge_i H_i y_{h(i)} = u_i(\boldsymbol{x}, \boldsymbol{y}) \Big]. \tag{4}$$

5. *Elimination of Equalities Containing $\boldsymbol{x}$.* *Solve equations of the form $H_i y_{h(i)} = u_i(\boldsymbol{x}, \boldsymbol{y})$, where $u_i(\boldsymbol{x}, \boldsymbol{y})$ is a constructor term containing $\boldsymbol{x}$, in terms of $H_i y_{h(i)}$ such that the result is a set of equations in the selector language. For example, with $\alpha = (\mathsf{s}_1^\alpha, \mathsf{s}_2^\alpha)$, the solution set of $\mathsf{s}_2^\alpha y = \alpha(\alpha(x_1, y_1), y_2)$ is*

$$x_1 = \mathsf{s}_1^\alpha \mathsf{s}_1^\alpha \mathsf{s}_2^\alpha y, \quad y_1 = \mathsf{s}_2^\alpha \mathsf{s}_1^\alpha \mathsf{s}_2^\alpha y, \quad y_2 = \mathsf{s}_2^\alpha \mathsf{s}_2^\alpha y.$$

Solving $\bigwedge_i H_i y_{h(i)} = u_i(\boldsymbol{x}, \boldsymbol{y})$ and eliminating all x's occurring in solved equations, we obtain

$$\exists \boldsymbol{x} : \Big[\bigwedge_i x_{f^{(2)}(i)} \neq t_i^{(2)}(\boldsymbol{x}, \boldsymbol{y}) \wedge \bigwedge_i G_i^{(2)} y_{g^{(2)}(i)} \neq s_i^{(2)}(\boldsymbol{x}, \boldsymbol{y}) \wedge \bigwedge_i H_i^{(2)} y_{h^{(2)}(i)} = H_i^{(3)} y_{h^{(3)}(i)} \Big]. \quad (5)$$

6. *Elimination of Constants.* *If for some $x \in \boldsymbol{x}$, $\mathsf{Is}_\mathsf{C}(x)$ appears in* (5)*, we instantiate x to each constant to eliminate $\exists x$. We still use* (5) *to denote the resulting formula.*
7. *Elimination of Quantifiers.* *Rewrite $\bigwedge_i G_i^{(2)} y_{g^{(2)}(i)} \neq s_i^{(2)}(\boldsymbol{x}, \boldsymbol{y})$ as*

$$\bigwedge_i G_i^{(3)} y_{g^{(3)}(i)} \neq s_i^{(3)}(\boldsymbol{x}, \boldsymbol{y}) \wedge \bigwedge_i G_i^{(4)} y_{g^{(4)}(i)} \neq s_i^{(4)}(\boldsymbol{y}),$$

where $\boldsymbol{x}$ do not appear in $s_i^{(4)}(\boldsymbol{y})$. Then (5) *can be rewritten as*

$$\exists \boldsymbol{x} : \Big[\bigwedge_i x_{f^{(2)}(i)} \neq t_i^{(2)}(\boldsymbol{x}, \boldsymbol{y}) \wedge \bigwedge_i G_i^{(3)} y_{g^{(3)}(i)} \neq s_i^{(3)}(\boldsymbol{x}, \boldsymbol{y}) \Big] \wedge \bigwedge_i G_i^{(4)} y_{g^{(4)}(i)} \neq s_i^{(4)}(\boldsymbol{y}) \wedge \bigwedge_i H_i^{(2)} y_{h^{(2)}(i)} = H_i^{(3)} y_{h^{(3)}(i)}. \quad (6)$$

We claim that

$$\exists \boldsymbol{x} : \Big[\bigwedge_i x_{f^{(2)}(i)} \neq t_i^{(2)}(\boldsymbol{x}, \boldsymbol{y}) \wedge \bigwedge_i G_i^{(3)} y_{g^{(3)}(i)} \neq s_i^{(3)}(\boldsymbol{x}, \boldsymbol{y}) \Big] \quad (7)$$

is valid and hence (6) *is equivalent to*

$$\bigwedge_i G_i^{(4)} y_{g^{(4)}(i)} \neq s_i^{(4)}(\boldsymbol{y}) \wedge \bigwedge_i H_i^{(2)} y_{h^{(2)}(i)} = H_i^{(3)} y_{h^{(3)}(i)}. \quad (8)$$

Theorem 1. *All transformations in Alg. 1 preserve equivalence.*

Theorem 2. *Alg. 1 eliminates a block of quantifiers in time $2^{O(n)}$.*

Theorem 3. $\mathsf{BC}_\mathsf{k}(\mathfrak{A}_\mathsf{TA})$ *is decidable in $O(\exp_k(n))$.*

5 Term Algebras with Length Function

In this section we introduce the extended theory and present the technical machinery needed to handle lengths of TA-terms in the elimination procedure.

Definition 4. *The structure of the extended language is* $\mathfrak{A}^{\mathbb{Z}}_{\mathsf{TA}} = (\mathfrak{A}_{\mathsf{TA}}; \mathfrak{A}_{\mathbb{Z}}; (.)^{\mathsf{L}} : \mathsf{TA} \to \mathbb{Z})$ *where* $\mathfrak{A}_{\mathsf{TA}}$ *is a term algebra,* $\mathfrak{A}_{\mathbb{Z}}$ *is Presburger arithmetic, and* $(.)^{\mathsf{L}}$ *denotes the length function; for a term* t, $(t^{\mathsf{L}})^{\mathfrak{A}^{\mathbb{Z}}_{\mathsf{TA}}} = \mathsf{len}(t^{\mathfrak{A}^{\mathbb{Z}}_{\mathsf{TA}}})$. *We denote by* $\mathscr{L}^{\mathbb{Z}}_{\mathsf{TA}}$ *the language for* $\mathfrak{A}^{\mathbb{Z}}_{\mathsf{TA}}$.

We call terms of sort TA (resp. $\mathbb{Z}$) TA-terms (resp. integer terms), similarly for constants, variables, quantifiers and formulae. We also use "term" for "TA" when there is no confusion. A TA-term can occur inside the length function. We call this type of occurrence integer occurrence to distinguish it from the normal term occurrence.

If $\boldsymbol{t}$ is a set of TA-terms, we use $\boldsymbol{t}^{\mathsf{L}}$ to denote the set of all integer occurrences, in the context, of the form $(Lt)^{\mathsf{L}}$ where $t \in \boldsymbol{t}$ and L denotes a (possibly empty) block of selectors.

Example 3. The formula $\exists x \exists y : \mathsf{TA}\ (x \neq y \wedge x^{\mathsf{L}} = y^{\mathsf{L}})$ states that there exists at least two distinct terms $t_1, t_2 \in \mathsf{TA}$ such that $\mathsf{len}(t_1) = \mathsf{len}(t_2)$. Note that the first occurrence of x is an ordinary term while the second one is integral. The same for the occurrences of y.

Instead of writing $\boldsymbol{n} = \boldsymbol{t}^{\mathsf{L}}$ to indicate the connection between term variables and the corresponding integer variables, we abuse the notation a bit by using $\boldsymbol{t}^{\mathsf{L}}$ as formal variables directly in Presburger formulae. For example, $\exists \boldsymbol{x}^{\mathsf{L}} : \mathbb{Z}\ \theta_{\mathbb{Z}}(\boldsymbol{x}^{\mathsf{L}}) \to \exists \boldsymbol{x} : \mathsf{TA}\ \theta_{\mathsf{TA}}(\boldsymbol{x})$ stands for $\forall \boldsymbol{x}^{\mathsf{L}} : \mathbb{Z} \left[\theta_{\mathbb{Z}}(\boldsymbol{x}^{\mathsf{L}}) \to \exists \boldsymbol{x} : \mathsf{TA}\ \theta_{\mathsf{TA}}(\boldsymbol{x})\right]$, which in turn is a shorthand for $\forall \boldsymbol{n} : \mathbb{Z} \left[\theta_{\mathbb{Z}}(\boldsymbol{n}) \to \exists \boldsymbol{x} : \mathsf{TA}\ (\theta_{\mathsf{TA}}(\boldsymbol{x}) \wedge \boldsymbol{n} = \boldsymbol{x}^{\mathsf{L}})\right]$.

5.1 Counting Constraints

As before, to eliminate $\exists \boldsymbol{x}$ from $\exists \boldsymbol{x} : \mathsf{TA}\ \theta_{\mathsf{TA}}(\boldsymbol{x}, \boldsymbol{y})$, we first put $\exists \boldsymbol{x} : \mathsf{TA}\ \theta_{\mathsf{TA}}(\boldsymbol{x}, \boldsymbol{y})$ into solved form. However, this alone does not suffice as the constraints on the lengths of $\boldsymbol{x}$ may restrict the solution set of $\boldsymbol{x}$.

Example 4. The truth value of $\exists x_1\ \exists x_2 : \mathsf{TA}\ (x_1 \neq x_2 \wedge x_1^{\mathsf{L}} = x_2^{\mathsf{L}} = 3)$ depends on the existence of two distinct terms of length 3.

Hence we need to know the number of distinct TA-terms at certain length.

Definition 5 (Counting Constraint). *A* counting constraint *is a predicate* $\mathsf{CNT}^{\alpha}_{k,n}(x)$ *($k > 0, n \geq 0$) that is* true *if and only if there are at least $n+1$ different α-terms of length x in $\mathfrak{A}_{\mathsf{TA}}$ with k constants.* $\mathsf{CNT}_{k,n}(x)$ *is similarly defined with α-terms replaced by* TA*-terms.*

Example 5. For $\mathfrak{A}^{\mathbb{Z}}_{\mathsf{list}} = (\mathfrak{A}_{\mathsf{list}}; \mathfrak{A}_{\mathbb{Z}})$ with one constant, $\mathsf{CNT}^{\mathsf{cons}}_{1,n}(x)$ is $x \geq 2m-1 \wedge 2 \nmid m$ where m is the least number such that the m-th Catalan number $C_m = \frac{1}{m}\binom{2m-2}{m-1}$ is greater than n. This is not surprising as C_m gives the number of binary trees with m leaves (that tree has $2m-1$ nodes).

Lemma 1 ([24]). $\mathsf{CNT}^{\alpha}_{k,n}(x)$ *and* $\mathsf{CNT}_{k,n}(x)$ *are expressible in Presburger arithmetic.*

5.2 Equality Completion

Often formulae do not have all the information required to construct counting constraints. Consider the formula $\exists x : \mathsf{TA}(y_1 \neq x \wedge y_2 \neq x \wedge y_1 \neq y_2)$. Without knowing equality relations between the lengths of x, y_1 and y_2, we can not find the integer constraint on the length of x. So in order to construct counting constraints, we need equality information between terms and equality information between lengths of terms.

Definition 6 (Equality Completion). *Let S be a set of* TA*-terms. An* equality completion *θ of S is a formula consisting of the following literals: for any $u, v \in S$, exactly one of $u = v$ and $u \neq v$, and exactly one of $u^{\mathsf{L}} = v^{\mathsf{L}}$ and $u^{\mathsf{L}} \neq v^{\mathsf{L}}$ are in θ.*

Let θ be a conjunction of literals. We say that θ' is an equality completion of θ, if θ' is a conjunction of an equality completion of $\Sigma(\theta)$ and tester literals in θ. We are only interested in compatible equality completions, i.e., θ is a subformula of θ'.

Example 6. Let $\mathsf{ar}(\alpha) = 2$ and θ be $y \neq \alpha(x, z) \wedge \mathsf{Is}_\alpha(y)$, then $\Sigma(\theta) = \{x, y, z, \alpha(x, z)\}$. A possible equality completion of θ is

$$\mathsf{Is}_\alpha(y) \wedge y^{\mathsf{L}} = (\alpha(x, z))^{\mathsf{L}} \wedge x^{\mathsf{L}} = z^{\mathsf{L}} \wedge y^{\mathsf{L}} \neq x^{\mathsf{L}} \wedge \bigwedge_{t,t' \in \Sigma(\theta); t \not\equiv t'} t \neq t'. \tag{9}$$

5.3 Clusters

Equality completion is an expensive operation and it is hard to maintain if the subsequent operations generate new terms (as in Alg. 6). Revisiting $\exists x : \mathsf{TA}(y_1 \neq x \wedge y_2 \neq x \wedge y_1 \neq y_2)$, it is easily seen that we need to know whether $y_1 = y_2$ or not only if we have guessed $x^{\mathsf{L}} = y_1^{\mathsf{L}} = y_2^{\mathsf{L}}$. In fact it suffices to have the equality information between terms of the same length. This leads to the notion of clusters.

Definition 7 (Clusters). *Let $[t]$ denote the equivalence class containing t with respect to term equality. We say that $C = \{[t_0], \ldots, [t_n]\}$ is a* cluster *if $t_0, \ldots, t_n$ are pairwise disjoint terms of the same length.*

For notation simplicity we may assume that a cluster is a set with each member being an (arbitrarily chosen) representative of the corresponding equivalence class. A cluster is maximal if no superset of it is a cluster. A cluster C is closed if C is maximal and for any maximal C', $C \cap C' \neq \emptyset \rightarrow C = C'$. Two distinct closed clusters are said to be mutually independent. A cluster is α-typed (called α-cluster) if all of its elements are α-typed. The notions of maximality, closedness and mutual independence naturally generalize to typed clusters. Note that an untyped maximal cluster may contain more than one typed maximal cluster. The size of a cluster is the number of equivalence classes in it. The rank of a cluster C, written $\mathsf{rk}(C)$, is the length of its terms. Clusters are partially ordered by their ranks.

Example 7. In Ex. 6, formula (9) induces two mutually independent clusters $C_1 : \{[x], [z]\}$ and $C_2 : \{[y], [\alpha(x, z)]\}$ with C_2 be α-typed and $\mathsf{rk}(C_1) < \mathsf{rk}(C_2)$. In fact any equality completion induces a set of mutually independent clusters. As another example, the formula

$$x \neq y \wedge x \neq z \wedge x^{\mathsf{L}} = y^{\mathsf{L}} \wedge x^{\mathsf{L}} = z^{\mathsf{L}} \wedge \mathsf{ls}_{\alpha}(x) \wedge \mathsf{ls}_{\alpha}(y)$$

gives two maximal clusters $C'_1 : \{x, y\}$ and $C'_2 : \{x, z\}$, with C'_1 be a α-cluster. However, neither C'_1 nor C'_2 is closed and their ranks are incomparable.

5.4 Length Constraint Completion

In general, formulae are of the form $\exists \boldsymbol{x} : \mathsf{TA}\ \Big(\theta_{\mathsf{TA}}(\boldsymbol{x}, \boldsymbol{y}) \wedge \theta_{\mathbb{Z}}(\boldsymbol{x}^{\mathsf{L}}, \boldsymbol{y}^{\mathsf{L}})\Big)$, where the lengths of $\boldsymbol{x}$ have been constrained by $\theta_{\mathbb{Z}}(\boldsymbol{x}^{\mathsf{L}}, \boldsymbol{y}^{\mathsf{L}})$. For the construction of accurate length constraints for $\boldsymbol{x}$, we need to make $\theta_{\mathbb{Z}}(\boldsymbol{x}^{\mathsf{L}}, \boldsymbol{y}^{\mathsf{L}})$ "complete" in the sense defined below.

Definition 8 (Length Constraint Completion). *Let $\theta_{\mathsf{TA}}(\boldsymbol{x}, \boldsymbol{y})$ be a formula of $\mathscr{L}_{\mathsf{TA}}$ and $\theta_{\mathbb{Z}}(\boldsymbol{x}^{\mathsf{L}}, \boldsymbol{y}^{\mathsf{L}})$ be a formula of $\mathscr{L}_{\mathbb{Z}}$. Write $\theta_{\mathsf{TA}}(\boldsymbol{x}, \boldsymbol{y})$ as $\theta^{(1)}_{\mathsf{TA}}(\boldsymbol{x}, \boldsymbol{y}) \wedge \theta^{(2)}(\boldsymbol{y})$ such that $\theta^{(2)}(\boldsymbol{y})$ does not contain $\boldsymbol{x}$. We say a formula $\Theta_{\mathbb{Z}}(\boldsymbol{x}^{\mathsf{L}}, \boldsymbol{y}^{\mathsf{L}})$ is a* completion *of $\theta_{\mathbb{Z}}(\boldsymbol{x}^{\mathsf{L}}, \boldsymbol{y}^{\mathsf{L}})$ in $\boldsymbol{x}$ with respect to $\theta_{\mathsf{TA}}(\boldsymbol{x}, \boldsymbol{y})$ if the following formulae are valid:*

I. $\forall \boldsymbol{y} : \mathsf{TA}\ \forall \boldsymbol{x} : \mathsf{TA}\ \Big[\theta_{\mathsf{TA}}(\boldsymbol{x}, \boldsymbol{y}) \wedge \theta_{\mathbb{Z}}(\boldsymbol{x}^{\mathsf{L}}, \boldsymbol{y}^{\mathsf{L}}) \leftrightarrow \theta_{\mathsf{TA}}(\boldsymbol{x}, \boldsymbol{y}) \wedge \Theta_{\mathbb{Z}}(\boldsymbol{x}^{\mathsf{L}}, \boldsymbol{y}^{\mathsf{L}})\Big]$.

II. $\forall \boldsymbol{y} : \mathsf{TA}\ \forall \boldsymbol{x}^{\mathsf{L}} : \mathbb{Z}\ \Big[\theta^{(2)}(\boldsymbol{y}) \wedge \Theta_{\mathbb{Z}}(\boldsymbol{x}^{\mathsf{L}}, \boldsymbol{y}^{\mathsf{L}}) \rightarrow \exists \boldsymbol{x} : \mathsf{TA}\ \Big(\theta_{\mathsf{TA}}(\boldsymbol{x}, \boldsymbol{y}) \wedge \Theta_{\mathbb{Z}}(\boldsymbol{x}^{\mathsf{L}}, \boldsymbol{y}^{\mathsf{L}})\Big)\Big]$.

Example 8. Let $\mathsf{ar}(\alpha) = 2$, $\boldsymbol{x} = \{x_1, x_2, x_3\}$, $\boldsymbol{y} = \emptyset$, $\theta_{\mathsf{TA}}(x_1, x_2, x_3)$ be $\alpha(x_1, x_2) = x_3$ and $\theta_{\mathbb{Z}}(x_1^{\mathsf{L}}, x_2^{\mathsf{L}}, x_3^{\mathsf{L}})$ be $x_1^{\mathsf{L}} < x_3^{\mathsf{L}} \wedge x_2^{\mathsf{L}} < x_3^{\mathsf{L}}$. Consider the following formulae:

$$\begin{aligned}
&\Theta_{\mathbb{Z}} : x_1^{\mathsf{L}} + x_2^{\mathsf{L}} + 1 = x_3^{\mathsf{L}} \wedge x_1^{\mathsf{L}} > 0 \wedge x_2^{\mathsf{L}} > 0,\\
&\Theta^1_{\mathbb{Z}} : x_1^{\mathsf{L}} < x_3^{\mathsf{L}} \wedge x_2^{\mathsf{L}} < x_3^{\mathsf{L}} \wedge x_1^{\mathsf{L}} > 0 \wedge x_2^{\mathsf{L}} > 0,\\
&\Theta^2_{\mathbb{Z}} : x_1^{\mathsf{L}} + x_2^{\mathsf{L}} + 1 = x_3^{\mathsf{L}} \wedge x_1^{\mathsf{L}} > 5 \wedge x_2^{\mathsf{L}} > 5.
\end{aligned}$$

It is not hard to argue that $\Theta_{\mathbb{Z}}$ is a completion of $\theta_{\mathbb{Z}}(x_1^{\mathsf{L}}, x_2^{\mathsf{L}}, x_3^{\mathsf{L}})$ in $\boldsymbol{x}$ with respect to $\theta_{\mathsf{TA}}(x_1, x_2, x_3)$. However neither $\Theta^1_{\mathbb{Z}}$ nor $\Theta^2_{\mathbb{Z}}$ is such a completion. Though $\Theta^1_{\mathbb{Z}}$ satisfies [I], it does not satisfies [II], as the assignment $\{x_1^{\mathsf{L}} = 3, x_2^{\mathsf{L}} = 3, x_3^{\mathsf{L}} = 4\}$ can not be realized by any assignment for $\boldsymbol{x}$. On the other hand, $\Theta^2_{\mathbb{Z}}$ satisfies [II], but not [I], as the assignment $\{x_1 = a, x_2 = a, x_3 = \alpha(a, a)\}$, where a is a constant, falsifies $\Theta^2_{\mathbb{Z}}$.

For the construction of length constraint completion, we require that $\theta_{\mathsf{TA}}(\boldsymbol{x}, \boldsymbol{y}) \wedge \theta_{\mathbb{Z}}(\boldsymbol{x}^{\mathsf{L}}, \boldsymbol{y}^{\mathsf{L}})$ induce a set of closed clusters and be in a special form defined below.

Definition 9. *We say $\theta_{\mathsf{TA}}(\boldsymbol{x}, \boldsymbol{y}) \wedge \theta_{\mathbb{Z}}(\boldsymbol{x}^{\mathsf{L}}, \boldsymbol{y}^{\mathsf{L}})$ is in* strong solved form *(with respect to $\boldsymbol{x}$) if $\theta_{\mathsf{TA}}(\boldsymbol{x}, \boldsymbol{y})$ is in solved form and all literals of the form $Ly \neq t(\boldsymbol{x}, \boldsymbol{y})$, where $y \in \boldsymbol{y}$ and $t(\boldsymbol{x}, \boldsymbol{y})$ is a constructor term (properly) containing $\boldsymbol{x}$, are redundant.*

Example 9. In Ex. 6, formula (9) is not in strong solved form. However, it can be made into strong solved form by adding $\mathsf{s}_1^\alpha y \neq x$ or $\mathsf{s}_2^\alpha y \neq z$.

The following predicates are needed to describe the construction algorithm:

$$\begin{aligned}
\mathsf{Tree}(t) &: \exists x_1, \ldots, x_n \geq 0 \left(t^{\mathsf{L}} = \left(\textstyle\sum_{i=1}^{n} d_i x_i \right) + 1 \right), \\
\mathsf{Node}^\alpha(t, \boldsymbol{t}_\alpha) &: t^{\mathsf{L}} = \textstyle\sum_{i=1}^{\mathsf{ar}(\alpha)} t_i^{\mathsf{L}} + 1, \\
\mathsf{Tree}^\alpha(t) &: \exists \boldsymbol{t}_\alpha \Big(\mathsf{Node}^\alpha(t, \boldsymbol{t}_\alpha) \wedge \textstyle\bigwedge_{i=1}^{\mathsf{ar}(\alpha)} \mathsf{Tree}(t_i) \Big),
\end{aligned}$$

where $\boldsymbol{t}_\alpha$ stands for $t_1, \ldots, t_{\mathsf{ar}(\alpha)}$ and $d_1, \ldots, d_n$ are the distinct arities of constructors. The predicate $\mathsf{Tree}(t)$ is true if and only if t^{L} is the length of a well-formed TA-term. The predicate $\mathsf{Node}^\alpha(t, \boldsymbol{t}_\alpha)$ forces the length of an α-term with known children to be the sum of the lengths of its children plus 1. The predicate $\mathsf{Tree}^\alpha(t)$ states the length constraint of a well-formed α-term.

Algorithm 2 (Length Constraint Completion). *Input:* $\theta_{\mathsf{TA}}(\boldsymbol{x}, \boldsymbol{y}) \wedge \theta_{\mathbb{Z}}(\boldsymbol{x}^{\mathsf{L}}, \boldsymbol{y}^{\mathsf{L}})$*, where* $\theta_{\mathsf{TA}}(\boldsymbol{x}, \boldsymbol{y})$ *is a conjunction of literals in* $\mathscr{L}_{\mathsf{TA}}$ *and* $\theta_{\mathbb{Z}}(\boldsymbol{x}^{\mathsf{L}}, \boldsymbol{y}^{\mathsf{L}})$ *is a conjunction of literals in* $\mathscr{L}_{\mathbb{Z}}$*. Initially set* $\Theta_{\mathbb{Z}}(\boldsymbol{x}^{\mathsf{L}}, \boldsymbol{y}^{\mathsf{L}}) = \theta_{\mathbb{Z}}(\boldsymbol{x}^{\mathsf{L}}, \boldsymbol{y}^{\mathsf{L}})$*. For each term* t *occurring in* $\theta_{\mathsf{TA}}(\boldsymbol{x}, \boldsymbol{y})$*, add the following to* $\Theta_{\mathbb{Z}}(\boldsymbol{x}^{\mathsf{L}}, \boldsymbol{y}^{\mathsf{L}})$*.*

a. $t^{\mathsf{L}} = 1$*, if* t *is a constant.*
b. $t^{\mathsf{L}} = s^{\mathsf{L}}$*, if* $t = s$*.*
c. $\mathsf{Tree}(t)$*, if* t *is untyped.*
d. $\mathsf{Tree}^\alpha(t)$*, if* t *is* α*-typed.*
e. $\mathsf{Node}^\alpha(t, \boldsymbol{t}_\alpha)$*, if* t *is* α*-typed with children* $\boldsymbol{t}_\alpha$*.*
f. $\mathsf{CNT}_{k,n}(t^{\mathsf{L}})$*, if* t *occurs in an untyped clusters of size* $n+1$ *and* $\mathfrak{A}_{\mathsf{TA}}$ *has* k *constants.*
g. $\mathsf{CNT}^\alpha_{k,n}(t^{\mathsf{L}})$*, if* t *occurs in an* α*-cluster of size* $n+1$ *and* $\mathfrak{A}_{\mathsf{TA}}$ *has* k *constants.*

Lemma 2. *If* $\theta_{\mathsf{TA}}(\boldsymbol{x}, \boldsymbol{y}) \wedge \theta_{\mathbb{Z}}(\boldsymbol{x}^{\mathsf{L}}, \boldsymbol{y}^{\mathsf{L}})$ *is in strong solved form and induces a set of mutually independent clusters, then* $\Theta_{\mathbb{Z}}(\boldsymbol{x}^{\mathsf{L}}, \boldsymbol{y}^{\mathsf{L}})$ *computed by Alg. 2 is a completion of* $\theta_{\mathbb{Z}}(\boldsymbol{x}^{\mathsf{L}}, \boldsymbol{y}^{\mathsf{L}})$ *in* $\boldsymbol{x}$ *with respect to* $\theta_{\mathsf{TA}}(\boldsymbol{x}, \boldsymbol{y})$*.*

Lemma 3. *Alg. 2 computes* $\Theta_{\mathbb{Z}}(\boldsymbol{x}^{\mathsf{L}}, \boldsymbol{y}^{\mathsf{L}})$ *in time* $O(n)$*.*

6 A New Quantifier Elimination Procedure for $\mathsf{Th}(\mathfrak{A}^{\mathbb{Z}}_{\mathsf{TA}})$

In this section we expand Alg. 1 to an elimination procedure for $\mathsf{Th}(\mathfrak{A}^{\mathbb{Z}}_{\mathsf{TA}})$. Since $\mathscr{L}^{\mathbb{Z}}_{\mathsf{TA}}$ has two sorts, namely $\mathbb{Z}$ and TA, we need to show elimination of integer quantifiers as well as term quantifiers.

6.1 Eliminate Quantifiers on Integer Variables

We assume that formulae with quantifiers on integer variables are in the form

$$\exists \boldsymbol{z} : \mathbb{Z} \left(\theta_{\mathbb{Z}}(\boldsymbol{x}^{\mathsf{L}}, \boldsymbol{y}, \boldsymbol{z}) \wedge \theta_{\mathsf{TA}}(\boldsymbol{x}) \right), \tag{10}$$

where $\boldsymbol{y}$, $\boldsymbol{z}$ are integer variables and $\boldsymbol{x}$ are term variables. Since $\theta_{\mathsf{TA}}(\boldsymbol{x})$ is in $\mathscr{L}_{\mathsf{TA}}$, we can move $\theta_{\mathsf{TA}}(\boldsymbol{x})$ out of the scope of $\exists \boldsymbol{z}$, obtaining

$$\exists \boldsymbol{z} : \mathbb{Z}\ \theta_{\mathbb{Z}}(\boldsymbol{x}^{\mathsf{L}}, \boldsymbol{y}, \boldsymbol{z}) \wedge \theta_{\mathsf{TA}}(\boldsymbol{x}). \tag{11}$$

Now $\exists \boldsymbol{z} : \mathbb{Z}\ \theta_{\mathbb{Z}}(\boldsymbol{x}^{\mathsf{L}}, \boldsymbol{y}, \boldsymbol{z})$ is essentially a Presburger formula and we can proceed to remove the block of existential quantifiers using Cooper's method [5, 20]. In fact, we can defer the elimination of integer quantifiers until all term quantifiers have been eliminated.

6.2 Eliminate Quantifiers on Term Variables

We assume that formulae with quantifiers on term variables are in the form

$$\exists \boldsymbol{x} : \mathsf{TA}\left(\theta_{\mathsf{TA}}(\boldsymbol{x}, \boldsymbol{y}) \wedge \Psi_{\mathbb{Z}}(\boldsymbol{x}^{\mathsf{L}}, \boldsymbol{y}^{\mathsf{L}}, \boldsymbol{z})\right), \tag{12}$$

where $\boldsymbol{x}, \boldsymbol{y}$ are term variables, $\boldsymbol{z}$ are integer variables, and $\Psi_{\mathbb{Z}}(\boldsymbol{x}^{\mathsf{L}}, \boldsymbol{y}^{\mathsf{L}}, \boldsymbol{z})$ is an arbitrary Presburger formula. The following algorithm is based on Alg. 1. To save space, we do not list $\Psi_{\mathbb{Z}}(\boldsymbol{x}^{\mathsf{L}}, \boldsymbol{y}^{\mathsf{L}}, \boldsymbol{z})$ until needed.

Algorithm 3. *Input:* $\exists \boldsymbol{x} : \mathsf{TA}\left(\theta_{\mathsf{TA}}(\boldsymbol{x}, \boldsymbol{y}) \wedge \Psi_{\mathbb{Z}}(\boldsymbol{x}^{\mathsf{L}}, \boldsymbol{y}^{\mathsf{L}}, \boldsymbol{z})\right)$.
Run Alg. 1 up to Step [7]. Apply the following subprocedures successively unless noted otherwise.

1. *Equality Completion (Alg. 4).*
2. *Elimination of Equalities Containing* $\boldsymbol{x}$ *(Alg. 5).*
3. *Propagation of Disequalities of the Form* $Ly \neq t(\boldsymbol{x}, \boldsymbol{y})$ *(Alg. 6).*
4. *Reduction of Term Quantifiers to Integer Quantifiers (Alg. 7).*

The purpose of steps [1]- [3] is to transform (12) *to a formula in strong normal form which induces a set of mutually independent clusters. Therefore by Alg. 2 we can construct the length constraint completion for* $\boldsymbol{x}$ *which allows us to reduce term quantifiers to integer quantifiers.*

Algorithm 4 (Equality Completion). *We assume the input formula is in the form (renaming the first part of* (7)*)*

$$\exists \boldsymbol{x} : \mathsf{TA}\Big[\bigwedge_i x_{f(i)} \neq t_i(\boldsymbol{x}, \boldsymbol{y}) \wedge \bigwedge_i L_i y_{g(i)} \neq s_i(\boldsymbol{x}, \boldsymbol{y})\Big], \tag{13}$$

where t_i, s_j *are: (i) quantified variables* $\boldsymbol{x}$*, (ii) parameters* $\boldsymbol{y}$*, (iii) selector terms of parameters in the form* Ly $(y \in \boldsymbol{y})$*, (iv) constants in* $\mathcal{A}$*, or (v) constructor terms built from terms in (i)-(iv). Let* S *be all terms including subterms which appear in* (13)*. Guess an equality completion of* S*. It is easily seen that an equality completion is of the form (omitting integer literals)*

$$\exists \boldsymbol{x} : \mathsf{TA}\Big[\bigwedge_i x_{f(i)} \neq t_i(\boldsymbol{x}, \boldsymbol{y}) \wedge \bigwedge_i L_i y_{g(i)} \neq s_i(\boldsymbol{x}, \boldsymbol{y}) \wedge \bigwedge_i x_{f'(i)} = t'_i(\boldsymbol{x}, \boldsymbol{y}) \wedge \bigwedge_i L'_i y_{g'(i)} = s'_i(\boldsymbol{x}, \boldsymbol{y})\Big]. \tag{14}$$

Algorithm 5 (Elimination of Equalities Containing x). *Let $\mathcal{E}$ denote the set of equalities containing $\boldsymbol{x}$. Exhaustively apply the following subprocedures until $\mathcal{E}$ is empty. Pick an $E \in \mathcal{E}$.*

A. *E is $x = u$. Then we know x does not occur in u and hence we can remove $\exists x$ by substituting u for all occurrences of x.*
B. *E is $Ly = \alpha(t_1(\boldsymbol{x}, \boldsymbol{y}), \ldots, t_k(\boldsymbol{x}, \boldsymbol{y}))$. Then replace E by*

$$\mathsf{s}_1^\alpha Ly = t_1(\boldsymbol{x}, \boldsymbol{y}),\ \ldots,\ \mathsf{s}_k^\alpha Ly = t_k(\boldsymbol{x}, \boldsymbol{y}).$$

C. *E is $\beta(u_1(\boldsymbol{x}, \boldsymbol{y}), \ldots, u_l(\boldsymbol{x}, \boldsymbol{y})) = \beta(u_1'(\boldsymbol{x}, \boldsymbol{y}), \ldots, u_l'(\boldsymbol{x}, \boldsymbol{y}))$. Then replace E by*

$$u_1(\boldsymbol{x}, \boldsymbol{y}) = u_1'(\boldsymbol{x}, \boldsymbol{y}),\ \ldots,\ u_l(\boldsymbol{x}, \boldsymbol{y}) = u_l'(\boldsymbol{x}, \boldsymbol{y}).$$

Algorithm 6 (Propagation of Disequalities of the Form $Ly \neq t(\boldsymbol{x}, \boldsymbol{y})$). *We only need to propagate those disequalities of the form $Ly \neq t(\boldsymbol{x}, \boldsymbol{y})$ such that $(Ly)^\mathsf{L} = (t(\boldsymbol{x}, \boldsymbol{y}))^\mathsf{L}$ and $t(\boldsymbol{x}, \boldsymbol{y})$ is a constructor term (properly) containing $\boldsymbol{x}$. This is done by the following sequence of disjunctive splittings.*

Let $\mathcal{D}$ denote the set of disequalities of the above form. Exhaustively apply the following subprocedures until $\mathcal{D}$ is empty. Pick $D : Ly \neq \alpha(t_1(\boldsymbol{x}, \boldsymbol{y}), \ldots, t_k(\boldsymbol{x}, \boldsymbol{y})) \in \mathcal{D}$.

A. *Disequality Splitting. Remove D from $\mathcal{D}$ and add to $\theta_{\mathsf{TA}}(\boldsymbol{x}, \boldsymbol{y})$*

$$\neg \mathsf{Is}_\alpha(Ly) \vee \bigvee_{1 \leq i \leq k} \mathsf{s}_i^\alpha Ly \neq t_i(\boldsymbol{x}, \boldsymbol{y}).$$

Return if we take $\neg \mathsf{Is}_\alpha(Ly)$; continue otherwise.
B. *Length Splitting. Suppose we take $\mathsf{s}_j^\alpha Ly \neq t_j(\boldsymbol{x}, \boldsymbol{y})$ $(1 \leq j \leq k)$. Split on*

$$(\mathsf{s}_j^\alpha Ly)^\mathsf{L} = (t_j(\boldsymbol{x}, \boldsymbol{y}))^\mathsf{L} \vee (\mathsf{s}_j^\alpha Ly)^\mathsf{L} \neq (t_j(\boldsymbol{x}, \boldsymbol{y}))^\mathsf{L}.$$

Return if we take $(\mathsf{s}_j^\alpha Ly)^\mathsf{L} \neq (t_j(\boldsymbol{x}, \boldsymbol{y}))^\mathsf{L}$; continue otherwise.
C. *Equality Splitting. Suppose the cluster of $t_j(\boldsymbol{x}, \boldsymbol{y})$ contains $u_0, \ldots, u_n$. Split on*

$$\bigvee_{i \leq n} \mathsf{s}_j^\alpha Ly = u_i \vee \bigwedge_{i \leq n} \mathsf{s}_j^\alpha Ly \neq u_i$$

In case we take any disjunct $\mathsf{s}_j^\alpha Ly = u_i$, return if u_i does not contain $\boldsymbol{x}$; rerun Alg. 5 otherwise. Note that Alg. 5 can only be rerun finitely many times as each run will remove at least one existentially quantified variable.
The last case is that we choose $\bigwedge_{i \leq n} \mathsf{s}_j^\alpha Ly \neq u_i$. This in general will increase the size of $\mathcal{D}$ if some of $u_i(\boldsymbol{x})$'s are also constructor terms containing $\boldsymbol{x}$. However if this happens, $u_i(\boldsymbol{x})$'s will sit in a cluster whose rank is lower than that of the cluster of $\alpha(t_1(\boldsymbol{x}, \boldsymbol{y}), \ldots, t_k(\boldsymbol{x}, \boldsymbol{y}))$. As the rank ordering is well-founded, eventually the size of $\mathcal{D}$ will decrease.

Algorithm 7 (Reduction of Term Quantifiers to Integer Quantifiers). *Omitting the redundant disequalities of the form $Ly \neq t(\boldsymbol{x}, \boldsymbol{y})$, we may assume the resulting formula be*

$$\exists \boldsymbol{x} : \mathsf{TA} \left[\theta^{(1)}_{\mathsf{TA}}(\boldsymbol{x}, \boldsymbol{y}) \wedge \theta^{(2)}_{\mathsf{TA}}(\boldsymbol{y}) \wedge \theta_{\mathbb{Z}}(\boldsymbol{x}^{\mathsf{L}}, \boldsymbol{y}^{\mathsf{L}}) \wedge \Psi_{\mathbb{Z}}(\boldsymbol{x}^{\mathsf{L}}, \boldsymbol{y}^{\mathsf{L}}, \boldsymbol{z}) \right], \tag{15}$$

where $\theta^{(1)}_{\mathsf{TA}}(\boldsymbol{x}, \boldsymbol{y})$ is of the form $\bigwedge_i x_{f(i)} \neq t_i(\boldsymbol{x}, \boldsymbol{y})$, $\theta^{(2)}_{\mathsf{TA}}(\boldsymbol{y})$ does not contain $\boldsymbol{x}$, $\theta_{\mathbb{Z}}(\boldsymbol{x}^{\mathsf{L}}, \boldsymbol{y}^{\mathsf{L}})$ is the integer constraint obtained from Algs. 4, 6 (Step [B]), and $\Psi_{\mathbb{Z}}(\boldsymbol{x}^{\mathsf{L}}, \boldsymbol{y}^{\mathsf{L}}, \boldsymbol{z})$ is the PA formula not listed before for simplicity. Now let $\theta_{\mathsf{TA}}(\boldsymbol{x}, \boldsymbol{y})$ denote $\theta^{(1)}_{\mathsf{TA}}(\boldsymbol{x}, \boldsymbol{y}) \wedge \theta^{(2)}_{\mathsf{TA}}(\boldsymbol{y})$. Call Alg. 2 to get the completion $\Theta_{\mathbb{Z}}(\boldsymbol{x}^{\mathsf{L}}, \boldsymbol{y}^{\mathsf{L}})$ of $\theta_{\mathbb{Z}}(\boldsymbol{x}^{\mathsf{L}}, \boldsymbol{y}^{\mathsf{L}})$ in $\boldsymbol{x}$ with respect to $\theta_{\mathsf{TA}}(\boldsymbol{x}, \boldsymbol{y})$. Now we claim that (15) *is equivalent to*

$$\exists \boldsymbol{x} : \mathsf{TA} \left[\theta^{(1)}_{\mathsf{TA}}(\boldsymbol{x}, \boldsymbol{y}) \wedge \theta^{(2)}_{\mathsf{TA}}(\boldsymbol{y}) \wedge \Theta_{\mathbb{Z}}(\boldsymbol{x}^{\mathsf{L}}, \boldsymbol{y}^{\mathsf{L}}) \wedge \Psi_{\mathbb{Z}}(\boldsymbol{x}^{\mathsf{L}}, \boldsymbol{y}^{\mathsf{L}}, \boldsymbol{z}) \right], \tag{16}$$

which in turn is equivalent to

$$\exists \boldsymbol{x}^{\mathsf{L}} : \mathbb{Z} \left[\theta^{(2)}_{\mathsf{TA}}(\boldsymbol{y}) \wedge \Theta_{\mathbb{Z}}(\boldsymbol{x}^{\mathsf{L}}, \boldsymbol{y}^{\mathsf{L}}) \wedge \Psi_{\mathbb{Z}}(\boldsymbol{x}^{\mathsf{L}}, \boldsymbol{y}^{\mathsf{L}}, \boldsymbol{z}) \right]. \tag{17}$$

Lemma 4. *Algs. 4,5 and 6 produce a formula in strong normal form which induces a set of mutually independent clusters.*

Theorem 4. *All transformations in Alg. 3 preserve equivalence.*

Theorem 5. *Alg. 3 eliminates a block of quantifiers in time $2^{2^{O(n)}}$.*

Theorem 6. $\mathsf{BC}_k(\mathfrak{PI}^{\mathbb{Z}}_{\mathsf{TA}})$ *is decidable in $O(\exp_{2k}(n))$.*

7 Conclusion

We presented new quantifier elimination procedures for the theory of term algebras and for the extended theory with Presburger arithmetic. The elimination procedures deal with a block of quantifiers of the same type at one step. The complexity of one-step elimination is exponential (resp. double exponential) for the theory of term algebras (resp. for the theory of term algebras with integers).

The double exponential complexity is due to the propagation of literals of the form $Ly \neq t(\boldsymbol{x}, \boldsymbol{y})$ in a cluster. We believe that more refined length constraint construction will remove this costly operation.

We plan to apply these methods to the first-order theory of queues [21] and to the first-order theory of Knuth-Bendix order [23].
