Term Algebras

Quantifier Elimination

QE for TA

Term Algebras with Integers

QE for "TA + Int"

Complexity

Future Work

- Term algebras can model a wide range of tree-like data structures.
- To verify programs we need to reason about these data structures.
- Programming languages often involve multiple data domains, resulting in verification conditions that span multiple theories.
- Common “mixed” constraints are combinations of data structures with integer constraints on the size of those structures.

# Bounded Quantifier Elimination

Introduction

● Motivation

● BQE

● Outline

Term Algebras

Quantifier Elimination

QE for TA

Term Algebras with Integers

QE for "TA + Int"

Complexity

Future Work

## In Theory:

- Term algebras have nonelementary time complexity [FR79].

☞ The complexity lower bound remains the same for any sub-theories of term algebras [CL89, Vor96].

## In Practice:

- We rarely deal with formulae with a large quantifier alternation depth.

☞ Therefore it is worthwhile to investigate the “bounded class” of formulae.

## Previous Work:

- We gave a quantifier-elimination procedure for the extended theory [ZSM04b].

☞ But no complexity upper bound is established.

Complexity

Future Work

**Definition 1** A term algebra  $\mathfrak{A}_{TA} : \langle TA; \mathcal{A}, \mathcal{C}, \mathcal{S}, \mathcal{T} \rangle$  consists of

1.  $TA$ : The term domain.
2.  $\mathcal{A}$ : A finite set of constants:  $a, b, c, \dots$
3.  $\mathcal{C}$ : A finite set of constructors:  $\alpha, \beta, \gamma, \dots$
4.  $\mathcal{S}$ : A finite set of selectors. For a constructor  $\alpha$  with arity  $k$ , there are  $k$  selectors  $s_1^\alpha, \dots, s_k^\alpha$  in  $\mathcal{S}$ .
5.  $\mathcal{T}$ : A finite set of testers. For each constructor  $\alpha$  there is a corresponding tester  $Is_\alpha$ .

☞ Two Properties:

- The data domain is the set of data objects generated exclusively by applying constructors.
- Each data object is uniquely generated.

# Definitions and Notations

Introduction

Term Algebras

● Term Algebras

● Definitions and Notations

● Axiomatization

● Example: LISP lists

Quantifier Elimination

QE for TA

Term Algebras with Integers

QE for "TA + Int"

Complexity

Future Work

- $\alpha = (s_1^\alpha, \dots, s_k^\alpha)$  means that  $\alpha$  is a constructor with  $\text{ar}(\alpha) = k$  and  $s_1^\alpha, \dots, s_k^\alpha$  are the corresponding selectors of  $\alpha$ .
- A term  $t$  is a **constructor term** ( $C$ -term) if the outmost function symbol of  $t$  is a constructor.
- A term  $t$  is a **selector term** ( $S$ -term) if the outmost function symbol of  $t$  is a selector.
- We assume that no constructor term appears inside selectors as simplification can always be done. For example,

$$s_i^\alpha(\alpha(x_1, \dots, x_k)) \quad \text{simplifies to} \quad x_i.$$

- $L, M, N, \dots$  denote selector sequences. For  $L = s_1, \dots, s_n$ ,  $Lx$  stands for

$$s_1(\dots(s_n(x) \dots)).$$

- A selector term  $s_i^\alpha(t)$  is called **proper** if  $\text{Is}_\alpha(t)$  holds.

## ■ Construction vs. selection.

$$s_i^\alpha(x) = y \leftrightarrow \exists \bar{z}_\alpha (\alpha(\bar{z}_\alpha) = x \wedge y = z_i) \vee (\forall \bar{z}_\alpha (\alpha(\bar{z}_\alpha) \neq x) \wedge x = y).$$

## ■ Unification closure. $\alpha(\mathbf{x}_\alpha) = \alpha(\mathbf{y}_\alpha) \rightarrow \bigwedge_{1 \leq i \leq \text{ar}(\alpha)} x_i = y_i.$

## ■ Acyclicity. $t(x) \neq x$ , if $t$ is built solely by constructors and $t$ properly contains $x$ .

## ■ Uniqueness. $\alpha(\mathbf{x}_\alpha) \neq \beta(\mathbf{y}_\beta)$ , $a \neq b$ , and $a \neq \alpha(\mathbf{x}_\alpha)$ , if $a$ and $b$ are distinct atoms and if $\alpha$ and $\beta$ are distinct constructors.

## ■ Domain closure.

$$\text{Is}_\alpha(x) \leftrightarrow \exists \bar{z}_\alpha \alpha(\bar{z}_\alpha) = x, \quad \text{Is}_A(x) \leftrightarrow \bigwedge_{\alpha \in \mathcal{C}} \neg \text{Is}_\alpha(x).$$

Term Algebras with Integers

QE for "TA + Int"

Complexity

Future Work

Signature:

$\langle \text{list}; \{\text{nil}\}; \{\text{cons}\}; \{\text{car}, \text{cdr}\}; \{\text{Is}_A, \text{Is}_{\text{cons}}\} \rangle$

Axioms:

$$(1) \text{Is}_A(x) \leftrightarrow \neg \text{Is}_{\text{cons}}(x), \quad (2) \text{car}(\text{cons}(x, y)) = x,$$

$$(3) \text{cdr}(\text{cons}(x, y)) = y, \quad (4) \text{Is}_A(x) \leftrightarrow \{\text{car}, \text{cdr}\}^+(x) = x,$$

$$(5) \text{Is}_{\text{cons}}(x) \leftrightarrow \text{cons}(\text{car}(x), \text{cdr}(x)) = x.$$

Formulas:

■  $\text{cons}(y, z) = \text{cons}(\text{cdr}(x), z) \rightarrow \text{cons}(\text{car}(x), y) = x$  (valid).

■  $x = \text{cons}(y, y) \rightarrow \text{cons}(\text{car}(x), y) = x$  (valid).

# Quantifier Elimination Preliminary

Introduction

Term Algebras

Quantifier Elimination

● QE Preliminary

● Solved Form

QE for TA

Term Algebras with Integers

QE for "TA + Int"

Complexity

Future Work

- It is well-known that eliminating arbitrary quantifiers reduces to eliminating existential quantifiers from formulae in the form

$$\exists x(A_1(x) \wedge \dots \wedge A_n(x)), \quad (1)$$

where  $A_i(x)$  ( $1 \leq i \leq n$ ) are literals [Hod93].

- We can also assume that  $A'_i$ 's are not of the form  $x = t$  as

$$\exists x(x = t \wedge \theta(x, \mathbf{y}))$$

simplifies to

- ◆  $\theta(t, \mathbf{y})$ , if  $x$  does not occur in  $t$ ;
- ◆  $\exists x\theta(x, \mathbf{y})$ , if  $t \equiv x$ ;
- ◆ false, if  $t$  is a constructor term properly containing  $x$ .

# Solved Form

Introduction

Term Algebras

Quantifier Elimination

● QE Preliminary

● Solved Form

QE for TA

Term Algebras with Integers

QE for "TA + Int"

Complexity

Future Work

**Definition 2 (Solved Form)** We say  $\exists x \theta_{TA}(x, y)$  is in the **solved form** (with respect to  $x$ ),

*if  $x$  are not in equalities, not asserted to be constants and not inside selector terms.*

General Idea:

- ➡ An existential formula in solved form has solutions under any instantiation of parameters.

Procedure Outline:

- ➡ A sequence of equivalence-preserving transformations will bring the input formula into a disjunction of formulae in the solved form.
- ➡ The whole block of existential quantifiers  $\exists x$  can be eliminated by removing all literals containing  $x$  in the matrix.

Complexity

Future Work

**Definition 3**  $\Phi'$  is a **type completion** of  $\Phi$  if  $\Phi'$  is obtained from  $\Phi$  by adding tester predicates such that

for any term  $s(t)$  either  $Is_\alpha(t)$  (for some constructor  $\alpha$ ) or  $Is_A(t)$  is present in  $\Phi'$ .

**Example 1** A possible type completion for  $y = \text{car}(\text{cdr}(x))$  is

$$y = \text{car}(\text{cdr}(x)) \wedge Is_{\text{cons}}(x) \wedge Is_A(\text{cdr}(x)).$$

With this type information,  $y = \text{car}(\text{cdr}(x))$  simplifies to

$$y = \text{cdr}(x).$$

☞ Guess a type completion of  $\theta(x, y)$  and simplify every selector term to a proper one.

QE for "TA + Int"

Complexity

Future Work

Replace all selector terms containing  $x$  by the corresponding equivalent constructor terms.

**Example 2** Let  $\alpha = (s_1^\alpha, s_2^\alpha)$ .

$\exists x (s_1^\alpha x = y \wedge \varphi(x, y))$  can be rewritten as

$$\exists x_1 \exists x_2 (x_1 = y \wedge \varphi(\alpha(x_1, x_2), y)).$$

Similarly,  $\exists x (s_1^\alpha x \neq y \wedge \varphi(x, y))$  becomes

$$\exists x_1 \exists x_2 (x_1 \neq y \wedge \varphi(\alpha(x_1, x_2), y)).$$

- ➡ It may increase the number of existential quantifiers, but leaves parameters unchanged.
- ➡ In the following transformations,  $x$  never appear inside selector terms.

# Decompose Relations between $C$ -Terms.

Future Work

**Definition 4 (Counting Constraint)** A *counting constraint* is a predicate  $\text{CNT}_{k,n}^\alpha(x)$  ( $k > 0, n \geq 0$ ) that is **true** if and only if

*there are at least  $n+1$  different  $\alpha$ -terms of length  $x$  in  $\mathcal{A}_{\text{TA}}$  with  $k$  constants.  $\text{CNT}_{k,n}(x)$  is similarly defined with  $\alpha$ -terms replaced by TA-terms.*

**Example 4** For  $\mathcal{A}_{\text{list}}^{\mathbb{Z}} = (\mathcal{A}_{\text{list}}; \mathcal{A}_{\mathbb{Z}})$  with one constant,

$$\text{CNT}_{1,n}^{\text{cons}}(x) \quad \text{is} \quad x \geq 2m - 1 \wedge 2 \nmid x$$

where  $m$  is the least number such that the  $m$ -th **Catalan number**  $C_m = \frac{1}{m} \binom{2m-2}{m-1}$  is greater than  $n$ .

*Reason:  $C_m$  gives the number of binary trees with  $m$  leaves (that tree has  $2m - 1$  nodes).*

# Equality Completion

In order to construct counting constraints, we need equality information between terms and equality information between lengths of terms.

**Definition 5 (Equality Completion)** *Let  $S$  be a set of TA-terms. An **equality completion**  $\theta$  of  $S$  is a formula consisting of the following literals: for any  $u, v \in S$ , exactly one of  $u = v$  and  $u \neq v$ , and exactly one of  $u^L = v^L$  and  $u^L \neq v^L$  are in  $\theta$ .*

**Example 5** *Let  $\alpha = (s_1^\alpha, s_2^\alpha)$  and  $\theta$  be*

$$y \neq \alpha(x, z) \wedge \text{Is}_\alpha(y).$$

*A possible equality completion of  $\theta$  is*

$$\text{Is}_\alpha(y) \wedge y^L = (\alpha(x, z))^L \wedge x^L = z^L \wedge y^L \neq x^L \wedge \bigwedge_{t, t' \in \Sigma(\theta); t \neq t'} t \neq t'. \quad (7)$$

**Definition 6 (Clusters)** Let  $[t]$  denote the equivalence class containing  $t$  with respect to term equality. We say that

$$C = \{[t_0], \dots, [t_n]\}$$

is a **cluster** if  $t_0, \dots, t_n$  are pairwise unequal terms of the same length.

- A cluster is **maximal** if no superset of it is a cluster.
- A cluster  $C$  is closed if  $C$  is maximal and for any maximal  $C'$ ,

$$C \cap C' \neq \emptyset \rightarrow C = C'.$$

- Two distinct closed clusters are said to be **mutually independent**.
- The **rank** of a cluster  $C$ , written  $\text{rk}(C)$ , is the length of its terms.

Complexity

Future Work

For the construction of length constraint completion, we require that  $\theta_{\text{TA}}(x, y) \wedge \theta_{\mathbb{Z}}(x^L, y^L)$  be in “strong normal form”.

**Definition 8** We say  $\theta_{\text{TA}}(x, y) \wedge \theta_{\mathbb{Z}}(x^L, y^L)$  is in **strong solved form** (with respect to  $x$ )

if  $\theta_{\text{TA}}(x, y)$  is in solved form and all literals of the form

$$Ly \neq t(x, y),$$

where  $y \in \mathbf{y}$  and  $t(x, y)$  is a constructor term (properly) containing  $x$ , are redundant.

**Example 9** In Ex. 5, formula (7) is **not** in strong solved form. However, it can be made into strong solved form by adding

$$s_1^\alpha y \neq x \quad \text{or} \quad s_2^\alpha y \neq z.$$

# Notations

The following predicates are needed to describe the construction algorithm:

$$\begin{aligned}\text{Tree}(t) & : \exists x_1, \dots, x_n \geq 0 \left( t^L = \left( \sum_{i=1}^n d_i x_i \right) + 1 \right), \\ \text{Node}^\alpha(t, \mathbf{t}_\alpha) & : t^L = \sum_{i=1}^{\text{ar}(\alpha)} t_i^L + 1, \\ \text{Tree}^\alpha(t) & : \exists \mathbf{t}_\alpha \left( \text{Node}^\alpha(t, \mathbf{t}_\alpha) \wedge \bigwedge_{i=1}^{\text{ar}(\alpha)} \text{Tree}(t_i) \right),\end{aligned}$$

where

- $\mathbf{t}_\alpha$  stands for  $t_1, \dots, t_{\text{ar}(\alpha)}$ ,
- $d_1, \dots, d_n$  are the distinct arities of constructors.

**Algorithm 3 (Integer Quantifier Elimination)** *We assume that formulae with quantifiers on integer variables are in the form*

$$\exists z : \mathbb{Z} (\theta_{\mathbb{Z}}(x^{\perp}, y, z) \wedge \theta_{\text{TA}}(x)), \quad (10)$$

*where  $y, z$  are integer variables and  $x$  are term variables.*

*Since  $\theta_{\text{TA}}(x)$  is in  $\mathcal{L}_{\text{TA}}$ , we can move  $\theta_{\text{TA}}(x)$  out of the scope of  $\exists z$ , obtaining*

$$\exists z : \mathbb{Z} \theta_{\mathbb{Z}}(x^{\perp}, y, z) \wedge \theta_{\text{TA}}(x). \quad (11)$$

*Now  $\exists z : \mathbb{Z} \theta_{\mathbb{Z}}(x^{\perp}, y, z)$  is essentially a Presburger formula and we can proceed to remove the block of existential quantifiers.*

☞ In fact, we can defer the elimination of integer quantifiers until all term quantifiers have been eliminated.

Let  $\theta_{\text{TA}}(x, y)$  denote  $\theta_{\text{TA}}^{(1)}(x, y) \wedge \theta_{\text{TA}}^{(2)}(y)$ .

Call Alg. 2 to get the completion  $\Theta_{\mathbb{Z}}(x^L, y^L)$  of  $\theta_{\mathbb{Z}}(x^L, y^L)$  in  $x$  with respect to  $\theta_{\text{TA}}(x, y)$ .

Now we claim that (15) is equivalent to

$$\exists x : \text{TA} \left[ \theta_{\text{TA}}^{(1)}(x, y) \wedge \theta_{\text{TA}}^{(2)}(y) \wedge \Theta_{\mathbb{Z}}(x^L, y^L) \wedge \Psi_{\mathbb{Z}}(x^L, y^L, z) \right], \quad (16)$$

which in turn is equivalent to

$$\exists x^L : \mathbb{Z} \left[ \theta_{\text{TA}}^{(2)}(y) \wedge \Theta_{\mathbb{Z}}(x^L, y^L) \wedge \Psi_{\mathbb{Z}}(x^L, y^L, z) \right]. \quad (17)$$
