## Notes on Distinguishability

This notes present a technique to prove a lower bound on the number of states of any DFA that recognizes a given language. The technique can also be used to prove that a language is not regular. (By showing that for every $k$ one needs at least $k$ states to recognize the language.)

It will be helpful to keep in mind the following two languages over the alphabet $\Sigma=\{0,1\}$ as examples: the language $E Q=\left\{0^{n} 1^{n} \mid n \geq 1\right\}$ of strings containing a sequence of zeroes followed by an equally long sequence of ones, and the language $A=(0 \cup 1)^{*} \cdot 1 \cdot(0 \cup 1)$ of strings containing a 1 in the second-to-last position.

We start with the following basic notion.
Definition 1 (Distinguishable Strings) Let $L$ be a language over an alphabet $\Sigma$. We say that two strings $x$ and $y$ are distinguishable with respect to $L$ if there is a string $z$ such that $x z \in L$ and $y z \notin L$, or vice versa.

For example the strings $x=0$ and $y=00$ are distinguishable with respect to $E Q$, because if we take $z=1$ we have $x z=01 \in E Q$ and $y z=001 \notin L$. Also, the strings $x=00$ and $\mathrm{y}=01$ are distinguishable with respect to $A$ as can be seen by taking $z=0$.

On the other hand, the strings $x=0110$ and $y=10$ are not distinguishable with respect to $E Q$ because for every $z$ we have $x z \notin L$ and $y z \not \approx n L$.

Exercise 1 Find two strings that are not distinguishable with respect to $A$.
The intuition behind Definition 1 is captured by the following simple fact.
Lemma 1 Let $L$ be a language, $M$ be a DFA that decides $L$, and $x$ and $y$ be distinguishable strings with respect to $L$. Then the state reached by $M$ on input $x$ is different from the state reached by $M$ on input $y$.

Proof: Suppose by contradiction that $M$ reaches the same state $q$ on input $x$ and on input $y$. Let $z$ be the string such that $x z \in L$ and $y z \notin L$ (or vice versa). Let us call $q^{\prime}$ the state reached by $M$ on input $x z$. Note that $q^{\prime}$ is the state reached by $M$ starting from $q$ and given the string $z$. But also, on input $y z, M$ must reach the same state $q^{\prime}$, because $M$ reaches state $q$ given $y$, and then goes from $q$ to $q^{\prime}$ given $z$. This means that $M$ either accepts both $x z$ and $y z$, or it rejects both. In either case, $M$ is incorrect and we reach a contradiction.

Consider now the following generalization of the notion of distinguishability.
Definition 2 (Distinguishable Set of Strings) Let L be a language. A set of strings $\left\{x_{1}, \ldots, x_{k}\right\}$ is distinguishable if for every two distinct strings $x_{1}, x_{j}$ we have that $x_{i}$ is distinguishable from $x_{j}$.

For example one can verify that $\{0,00,000\}$ are distinguishable with respect to $E Q$ and that $\{00,01,10,11\}$ are distinguishable with respect to $A$.

We now prove the main result of this handout.
Lemma 2 (Main) Let $L$ be a language, and suppose there is a set of $k$ distinguishable strings with respect to $L$. Then every DFA for $L$ has at least $k$ states.

Proof: If $L$ is not regular, then there is no DFA for $L$, much less a DFA with less than $k$ states. If $L$ is regular, let $M$ be a DFA for $L$, let $x_{1}, \ldots, x_{k}$ be the distinguishable strings, and let $q_{i}$ be the state reached by $M$ after reading $x_{i}$. For every $i \neq j$, we have that $x_{i}$ and $x_{j}$ are distinguishable, and so $q_{i} \neq q_{j}$ because of Lemma 1 . So we have $k$ different states $q_{1}, \ldots, q_{k}$ in $M$, and so $M$ has at least $k$ states.

Using Lemma 2 and the fact that the strings $\{00,01,10,11\}$ are distinguishable with respect to $A$ we conclude that every DFA for $A$ has at least 4 states.

For every $k \geq 1$, consider the set $\left\{0,00, \ldots, 0^{k}\right\}$ of strings made of $k$ or fewer zeroes. It is easy to see that this is a set of distinguishable strings with respect to $E Q$. This means that there cannot be a DFA for $E Q$, because, if there were one, it would have to have at least $k$ states for every $k$, which is clearly impossible.
