

W4231: Analysis of Algorithms

12/7/1999

- Testing primality

– COMSW4231, Analysis of Algorithms –

1

The number of repetitions depends on how many prime numbers are there between 2^{499} and 2^{500} .

There are about $n/\ln n$ primes between 2 and n .

There are about $n/2\ln n$ primes between $n/2$ and n .

By picking a random odd number, there is a chance in $\ln n$ of picking a prime.

There are efficient $O((\log n)^3)$ time algorithms to check whether n is prime. The algorithms use randomness.

– COMSW4231, Analysis of Algorithms –

3

Fermat's Little Theorem

If n is prime, then for every $a \in \mathbf{Z}_n^*$,

$$a^{n-1} = 1 \pmod{n}$$

If, on input n , we find an a such that $a^{n-1} \neq 1 \pmod{n}$, then this proves that n is not prime.

– COMSW4231, Analysis of Algorithms –

5

Generating Big Random Primes

To generate a random 500 bits prime:

1. Pick a random odd number $2^{499} < n < 2^{500}$.
2. Check whether n is prime
3. If n is not prime, go to step 1.

– COMSW4231, Analysis of Algorithms –

2

General Idea for Randomized Primality Testing

On input a big integer n , want to decide whether it's prime or composite.

Use randomness.

Look for "evidence" that n is composite.

If can find evidence, say that n is composite. Otherwise say that n is prime.

– COMSW4231, Analysis of Algorithms –

4

Not a Necessary Condition

There are integers n (e.g. 561) that are not prime, yet for every $a \in \mathbf{Z}_n$, $a \neq 0$, we have $a^{n-1} = 1 \pmod{n}$.

They are called Carmichael Numbers, and there are infinitely many (but they are rare).

Theorem: If n is a Carmichael number, it cannot be a power of a prime.

– COMSW4231, Analysis of Algorithms –

6

Modular Square Roots

If n is prime, then the equation

$$x^2 = 1 \pmod{n}$$

has only two solutions in \mathbf{Z}_n : $x = 1$ and $x = (-1 \pmod{n})$.

If, on input n , we find an a such that $a \not\equiv 1 \pmod{n}$, $a \not\equiv -1 \pmod{n}$, but $a^2 = 1 \pmod{n}$, then this proves that n is not prime.

Proof

Suppose a is such that $a \not\equiv 1 \pmod{n}$, $a \not\equiv -1 \pmod{n}$, but $a^2 = 1 \pmod{n}$.

Then

$$(a+1)(a-1) = a^2 - 1 = 0 \pmod{n}$$

Since $(a+1)(a-1)$ is a multiple of n , and neither $(a+1)$ nor $(a-1)$ are a multiple of n , it follows that n is not prime, and that it has some factors in common with $(a-1)$ and some factors in common with $(a+1)$.

Rabin-Miller Test

On input integer n :

Pick a random a in $\{1, \dots, n-1\}$.

Compute $a^{n-1} \pmod{n}$ using the modular exponentiation algorithm (with repeated squaring).

If find nontrivial root of 1 at some stage of modular exponentiation, output composite. If $a^{n-1} \not\equiv 1 \pmod{n}$, output composite.

Otherwise output prime.

Details

```
MillerRabin( $n$ )
  pick random  $a$  in  $\{1, \dots, n-1\}$ 
   $e := a$ 
  for  $k = \lceil \log_2(n-1) \rceil - 1$  down to 1
    if  $e \not\equiv 1 \pmod{n}$  and  $e \not\equiv -1 \pmod{n}$ 
      and  $e * e = 1 \pmod{n}$ 
        return (composite)
     $e := e * e \pmod{n}$ 
    if  $k$ -th digit of  $(n-1)$  is 1
       $e := e * a \pmod{n}$ 
  if  $e \not\equiv 1 \pmod{n}$  return (composite)
  return (prime)
```

Correctness

If n is prime, then no matter how we choose a , the algorithm output the right answer, because it can never find a a such that $a^{n-1} \not\equiv 1 \pmod{n}$ and it can never find a non-trivial root of 1.

If n is composite, we want to prove that are choices of a for which the algorithm gives the right answer, and in fact the right answer is given with probability $> 1/2$.

Analysis of Error Probability in Miller-Rabin

Fix a composite n

Consider the set B of bad choices of a such that MillerRabin says that n is prime when the random choice a is made.

We want to prove $B < (n-1)/2$. We do so by proving that B is always contained in a **proper subgroup** of \mathbf{Z}_n^* .

Group

A group is a set G with an operation \otimes , that given two elements of G returns an element of G such that

1. For every $a, b \in G$, $a \otimes b = b \otimes a$;
2. For every $a, b, c \in G$, $(a \otimes b) \otimes c = a \otimes (b \otimes c)$;
3. There exists an element $u \in G$ such that for every $a \in G$, $a \otimes u = u \otimes a = a$;
4. For every element $a \in G$ there exists an element $a' \in G$ such that $a \otimes a' = u$.

Examples

\mathbf{Z}_n with the operation $\cdot + \cdot \pmod n$ is a group, $u = 0$.

\mathbf{Z}_n^* with the operation $\cdot * \cdot \pmod n$ is a group, $u = 1$.

Subgroup

Let G be a group with operation \otimes .

A subset $S \subset G$ is a subgroup if $u \in S$, and for every $a, b \in S$ we have $a \otimes b \in S$ and also $a', b' \in S$.

If G is a group and S is a subgroup of G , then S is also a group.

Theorem: If S is a subgroup of G then $|S|$ divides $|G|$.

Proof of Fermat's Little Theorem

Let n be prime.

Fix an element $a \in \mathbf{Z}_n^*$.

Consider the set $\{1, a, a^2 \pmod n, a^3 \pmod n, \dots\}$ of all possible powers of a . It is a subset of \mathbf{Z}_n^* , and so it is finite.

Then, at some point, we get a power that we have already seen: there are s, r , $0 \leq r < s \leq n - 1$ such that $a^s = a^r \pmod n$.

Consider the smallest s for which this happens, then $a^s = 1 \pmod n$.

Then the set of all possible powers of a is $P = \{1, a, a^2, \dots, a^{s-1}\}$ (all taken $\pmod n$).

P is a subgroup of \mathbf{Z}_n^* : it contains 1, the product of two powers of a is a product of a , and the inverse of $a^k \pmod n$ is $a^{s-k} \pmod n$.

The number of elements of P is s . Then s divides $n - 1$. So a^{n-1} is a power of a^s , and so $a^{n-1} = 1 \pmod n$.

Size of B , first case

Suppose n is composite and is not a Carmichael number. Then there is some $a \in \mathbf{Z}_n^*$ such that $a^{n-1} \neq 1 \pmod n$.

Define the set $G := \{a : a^{n-1} = 1 \pmod n\}$. This is a subgroup of \mathbf{Z}_n^* (verify) and it is a proper subgroup. Then $|G| \leq |\mathbf{Z}_n^*|/2 < (n - 1)/2$.

And also $B \subseteq G$, so $|B| < (n - 1)/2$.

Size of B , second case

Suppose n is a Carmichael number.

Then n has at least two different prime factors. We can write $n = n_1 n_2$ where $\gcd(n_1, n_2) = 1$.

Let t be the number of consecutive zeroes in the least significant digits of $n - 1$, i.e. write $n - 1 = 2^t u$ where u is odd.

For each a that could be picked at random in RabinMiller, consider the sequence

$$(a^u \bmod n, a^{2u} \bmod n, a^{4u} \bmod n, \dots, a^{2^t u} \bmod n)$$

These are intermediate values computed during the computation of $a^{n-1} \bmod n$.

Consider the largest j such that there is a v such that $v^{2^j u} = -1 \pmod n$. Fix the corresponding v .

Define $G = \{a : a^{2^j u} = \pm 1 \pmod n\}$.

Then:

- $B \subseteq G$,
- G is a subgroup of \mathbf{Z}_n^* ,
- there is an element $w \in \mathbf{Z}_n^*$ such that $w \notin G$.

Proving that $G \neq \mathbf{Z}_n^*$

Consider the system

$$\begin{aligned} x &= v \pmod{n_1} \\ x &= 1 \pmod{n_2} \end{aligned}$$

There is a $w \in \mathbf{Z}_n^*$ that satisfies the system.

When we raise w to $2^j u$ we have

$$\begin{aligned} w^{2^j u} &= -1 \pmod{n_1} \\ w^{2^j u} &= 1 \pmod{n_2} \end{aligned}$$

So it is impossible that $w^{2^j u} = 1 \pmod n$ or that $w^{2^j u} = -1 \pmod n$.

Then $w \notin G$.

Error Probability

Then for every composite n , the probability that Miller-Rabin makes a mistake (i.e. says that n is prime) is $< 1/2$.

If we take k Miller-Rabin tests, and say that n is prime iff all k tests indicate that is prime, then the probability of making a mistake becomes $1/2^k$.

Using $k = 50$ gives very high confidence.
